

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

Nov. 23.—“On the Application of Iron to the Purposes of War and Naval Construction.” By Wm. FAIRBAIRN, Esq., LL.D., F.R.S. On this evening the Duke of Somerset, K.G., will preside.

Nov. 30.—“On the Mechanical Conditions of Railway Working to Prevent Destructive Wear and Risk.” By W. BRIDGES ADAMS, Esq.

Dec. 7.—“On the Construction, Retardation, Safety, and Police of Railway Trains.” By W. BRIDGES ADAMS, Esq.

CANTOR LECTURES.

There will be three Courses of “Cantor” Lectures on the following subjects during the ensuing Session:—

“On the Relation of Science and Art to Manufactures.”

By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

“On the Application of Geology to the Arts and Manufactures.” By Professor D. T. ANSTED, M.A., F.R.S.

“On the Application of Chemistry to the Arts.” By Dr. F. CRAIG CALVERT, F.R.S.

Mr. B. Waterhouse Hawkins will commence his course on Monday evening, the 12th of December.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture. Particulars of the Courses will be duly announced in the *Journal*.

Proceedings of the Society.

FIRST ORDINARY MEETING.

Wednesday, November 16th, 1864; William Hawes, Esq., Chairman of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Bickerstaff, William Martin, 13, Highbury-terrace, N.
 Buseell, Charles, 26, Soho-square, W.
 Clauson, Charles A. R. (Messrs. Rogers, Bros., and Co.), Naples.
 Altachul, Dr. D. H., 9, Old Bond-street, W.
 Clutton, Robert, Hartswood, Raigate.
 Craven, Joseph, Dole Mill, Thornton, near Bradford, Yorks.
 Crowther, Wm., Chemical Works, Gomersal, near Leeds.
 Darkin, Charles James, 21, Victoria-terrace, Finchley-road, N.W.
 Dyer, George, 90, Regent-street, W.
 Eskell, Abraham, 8, Grosvenor-street, W.
 Evans, John James, Rose-bank, Rock-park, Birkenhead.
 Field, John Lyon, Upper Marsh, Lambeth, S.
 Ford, Herbert, 8, Pier-road, Erith, S.E.; and 1, Charlotte-row, Mansion-house, E.C.
 Frean, G. H., Mill-street, Dockhead, S.E.
 Gilbert, Arthur, 12, Claverton-street, Pimlico, S.W.
 Green, German, 7, Helmet-row, Saint Luke's, E.C.
 Hannah, Robert, 2, Alfred-place West, Brompton, S.W.
 Hart, John Matthias, 76, Chesapeake, E.C.
 Haysman, Jas., F.R.G.S., Burdett House, Burdett-rd., E.
 Hollow, Richard Welch (Lord Mayor of York), Mansion-house, York.
 Hudswell, W. S., New Railway Foundry, Leeds.
 Huggon, William, 30, Park-row, Leeds.
 Lainsou, Henry, Heath-house, Raigate.
 Leycester, George Percival, 6, Oak Hill, Hampstead-road, N.W.
 Locket, George, Acton-house, Roslyn-park, Hampstead, N.W.
 Mather, William, Chester-road, Manchester.
 Morris, Edward, 43, Parliament-street, S.W.
 Nosotti, Charles, 398, Oxford-street, W.
 Oertling, Ludwig (Ladd and Oertling), 27, Moorgate-st., E.C.
 Oram, John White, 7, Bank-buildings, E.C.
 Payne, James Bertrand, 44, Dover-street, W.
 Page, Nathaniel, Stag Brewery, Pimlico, S.W.
 Pankhurst, R. M., LL.D., South King-street, Manchester.
 Robinson, James Edward, Pontefract.
 Smith, Joseph, 3, Percy-villas, Wells-st., Hackney, N.E.
 Snooks, William, 6, Duke-street, London Bridge, S.E.
 Talbot, Robert, Strand-on-Green, Chiswick, W.
 Taylor, John, 45, Connaught-terrace, W.
 Tucker, Silas, 54, Canonbury-park south, N., and 234, High Holborn, W.C.
 Turnbull, Thomas, jun., Whitewell Dockyard, Whitby
 Venables, William Vernon, 6, Queen-street-place, E.C., and 20, Canonbury-villas, N.

Wagstaff, John Henry, 9, Sheldon-street, Bishop's-road, Paddington, W.
 Walker, W., jun., J.P., Red Hall, Shadwell, near Leeds
 Watkins, Major-General, B 3, Albany, W.
 Watson, Edward Façon, 201, Piccadilly, W.
 Watson, Thomas, 19, Highbury-crescent, N.
 Wentworth, J. W. T. Vernon, Wentworth Castle, Barnsley
 Whiteside, R. B., 49, Lime-street, E.C.
 Whitford, Edward Edmondson, 55, Lansdowne-road, Kensington-park, W.
 Willing, James, 366, Gray's-inn-road, W.C., and South Lodge, Ham, S.W.
 Wilson, Captain J. H., 35, Pembridge-villas, Bayswater, W.
 Wilson, George, Nunthorpe Hall, York.
 Wilson, Thomas, 20, Gloucester-square, Hyde-park, W.
 Woodthorpe, Edmund, 28A, Basinghall-street, E.C.
 Wrentmore, Francis, 250, Regent-street, W.
 Yallop, Thomas, 39, Norfolk-square, Hyde-park, W.

AND AS HONORARY CORRESPONDING MEMBERS.

Bonghi, Cavaliere Diego, 38, Vico S. Giuseppe de Midi, Naples.
 Knight, J. G., Melbourne, Victoria.

The CHAIRMAN delivered the following
ADDRESS.

My colleagues having done me the honour to elect me a second time to the office of Chairman of the Council of this Society, it becomes my duty to address you on the opening of the session 1864-65.

The important position the Society now holds among the educational and scientific institutions of this metropolis, the larger and broader views with which we are called upon to consider the various and important subjects to which our attention is necessarily directed, make it year by year more difficult to indicate in the opening address, in conformity with the bye-laws of the Society, the policy which is proposed to be pursued in each session; still this duty is imposed on the Council, and must be discharged; and I trust I shall show that the Council is now, as in previous years, fully alive to its duty.

In accordance with the ordinary custom followed by my predecessors, I must begin this annual address by paying a tribute of respect to the memory of the members of our Society whose loss by death we have to deplore during the past year. The number of members we have lost is unusually large—but as, under the improved management of our *Journal*, an obituary notice—where particulars have been obtained—of each member has appeared soon after his decease, it is unnecessary for me to do more this evening than notice those more especially distinguished in some branch of Arts, Manufactures, and Commerce.

Let me first state that the list of deceased members shows how we draw our members from all ranks and professions. The papers read before us are not, as in most other societies, devoted to one branch of science, and read to those whose attention has been especially

directed thereto; but papers relating to almost every branch of Art, Manufactures, and Commerce are either laid before the Council or read at our evening meetings to an audience which is brought together by the interest they take in each specific subject; and from this arises the peculiar freshness, vigour, and interest which distinguish our discussions, and which cannot be so often found at the meetings of any other society; to this must be attributed the fact of our members being derived from all classes of society.

We have lost in Lord Ashburton, who was a Vice-President of this Society, and for some time filled the office of President of the Geographical Society, a great patron of art, science, and literature, who devoted much of his time to the improvement of the moral and social condition of the working classes, and proved his desire to give a practical turn to education, by offering prizes to the scholars of the national schools for their knowledge of common things; and in 1854 he acted as chairman of one of our committees, which recommended that our Society should endeavour to promote the establishment of a normal school for the training of commercial schoolmasters.

In the Duke of Newcastle we have also lost a most distinguished member, whose engagements in public life prevented his taking so active a part as Lord Ashburton in the advancement of practical science, but who never failed to show great interest in whatever promoted the welfare of his country.

In art we have lost Mr. Dyce and Mr. J. D. Harding. Mr. Dyce, R.A., was the son of a physician at Aberdeen, where he was born in 1806, and educated at the Marischal College. He distinguished himself in early life by his attainments; and then, led by a love of art, entered the Schools of the Royal Scottish Academy. At the age of twenty he went to Italy, and spent sometime in the study of the great works of art at Rome and Florence, returning again in a few years to mature his earlier studies. After again passing two years on the Continent he returned to settle in Edinburgh, where he remained about eight years, devoted to historic art, in which he did not find encouragement, but practised chiefly as a portrait painter. Among his varied attainments he had acquired a knowledge of ornamental design; and in 1838 he was induced to accept the superintendence of the School of Design then established by the Government, and in that office and later, as Inspector and Member of the Council of the School, he continued his valuable aid towards its development till 1848, when he finally resigned. In the meanwhile, he had been one of the successful competitors in the Westminster Hall Fresco Exhibition, and in 1845

completed the first fresco on the walls of the new Legislative Palace—"The Baptism of St. Ethelbert." His previous studies, aided by a careful investigation and practice of the art of fresco-painting, had prepared him for the task, and his work was hailed as a success. In 1848 he was commissioned to decorate the Queen's Robing-room, with designs from "The Legend of King Arthur." Of these he only lived to complete five—one large and four smaller subjects, of unequal dimensions. The first typifies Hospitality—The admission of Sir Tristram to the Fellowship of the Round Table. The second, Religion or Faith—The vision of Sir Galahad and his Company. The third, Mercy—Sir Garwayne swearing to be Merciful and never to be against the Ladies. The fourth, Generosity—King Arthur, unhorsed, spared by Sir Launcelot. The fifth, Courtesy—Sir Tristram harping to La Reine Isonde. In these great works, the painter's genius, studied art, and profound learning and judgment have combined to produce a series of decorative paintings, stamped by a feeling of pure art, and admirably adapted by their skilful treatment to the decoration of the Palace. Mr. Dyce had, during his whole career, occasionally exhibited easel pictures; and he will be best remembered by his "King Joash shooting the arrow of deliverance," 1844; and his later works; "The Jacob and Rachel," 1853; "St. John leading home the Virgin," 1860; and "George Herbert, of Bemerton," 1861. His tastes were severe, his drawing and composition scholastic and accurate, and marked by a learned refinement. His colour positive, not graced by the refinements of tint, but well suited to the simplicity of his style. He died, 15th February, 1864, his death, it is to be feared, accelerated by the controversy which ensued on the delay in completing his frescoes in the Queen's Robing-room.

Mr. Harding also deserves notice in this address, although he did not occupy so high a position in Art as Mr. Dyce. He was a member of the old Water Colour Society, and his pictures obtained considerable celebrity, though he was, perhaps, better known to the public as the author of educational works relating to water-colour painting and drawing with the lead pencil, which still retain a high reputation, and are a most valuable contribution to the studies of the young artist and to the practical instruction of the amateur. It is not, I believe, too much to say that some popular art-critics owe a considerable portion of their success to the advantages they derived from constant association with Mr. Harding.

In practical mechanics we have to lament the death of Mr. Thomas Henry Maudslay, of London, and of Mr. Richard Roberts, of Manchester,

both distinguished for their great knowledge of mechanical engineering and for the large number of improvements they have introduced in machine tools and in steam and cotton machinery.

In agriculture we have lost Mr. Morton, the elder, and Mr. Beadel, both well known for the active part they took for many years at meetings of agricultural societies, where they always advocated the use of machinery and the most advanced system of farming, as the only means by which the agriculturalist could obtain a proper return for the industry and capital invested.

In literature we have lost Mr. Dilke. The connection of Mr. Dilke with the periodical literature of his time cannot fail to be interesting to our members, and deserves a special record in this address. During his long life he was connected with art, science, and literature, and was elected a member of this Society in 1849. He was almost the first to rely upon the desire of the great mass of the middle class to obtain information connected with art and literature, if it could be provided at a rate which would bring it within their reach; and, carrying this view into practical operation, he reduced, in the year 1831, the price of the *Athenæum* from 8d. to 4d., at the same time enlarging its size and improving the character of its intelligence. At a later period, when connected with the *Daily News*, and before the repeal of the stamp duty on newspapers, in 1846, he reduced the price of this daily journal to 2½d.

In addition to these, I have to notice the death of Sir Wm. Brown, Bart., a distinguished merchant, who, having acquired a large fortune, became a most liberal donor to every institution likely to promote the improvement of the people, and but a year or two before his death built at his own expense and presented to the borough of Liverpool a magnificent library and museum, to be opened free to all the inhabitants of the borough.

In concluding this obituary notice I must not omit expressing the regret of the Council at the sudden loss of one of its younger but very active members, Mr. Frederick Lawrence, whose energy and talent made him a very valuable member of our body.

Before proceeding to the ordinary business of the evening, I must remind you of the very gratifying meeting of this Society which took place in Willis's Rooms, in June last, when His Royal Highness the Prince of Wales, our President, presided over a very large meeting of the Society, and performed, in a most gracious and pleasing manner, the duty of presenting the medals of the Society and other honourable rewards to the persons selected by the Council to receive them. The meeting was of unusual interest, not only on account of its being the first

occasion on which His Royal Highness had presided over a meeting of the Society, but also from the nature and number of the prizes distributed, and the distinguished characters of those who received them. The members are aware that a portion of the subscription raised to record the high sense the Society entertained of the great services rendered to it by its late lamented President, the Prince Consort, was appropriated to the execution of dies for a gold medal, to be given annually to whoever, in the opinion of the Council, had in the greatest degree promoted Arts, Manufactures, and Commerce. The Council, on this occasion of presenting the first medal, through the hands of His Royal Highness the President, selected, I may say by acclamation, Sir Rowland Hill, K.C.B., the originator of the penny postage, as well as of those most complicated arrangements required to carry this new system successfully into practical operation—a merit perhaps greater than that due to him for the original idea—as pre-eminently entitled to receive this testimony of his valuable services. It is not too much to say that Sir Rowland Hill, by this bold conception, has facilitated most materially the commercial transactions of the empire; has greatly promoted the progress of Arts and Manufactures; has given a stimulus to the desire of education amongst the rising generation; and, by facilitating the intercourse between all classes, has materially contributed to improve the social and moral condition of the people. No one will doubt his title to receive from this Society the first Albert Gold Medal. The next prize, the Swiney Prize, consisting of a silver goblet, value one hundred pounds, containing one hundred sovereigns, the proceeds of a legacy left to the Society by Dr. Swiney, to be given, once in every five years, to the "Author of the best published treatise on Jurisprudence," was, on the recommendation of a Committee, consisting of Vice-Chancellor Sir W. P. Wood, Sir Thos. Phillips, and G. W. Hastings, Esq., and others, adjudged to a distinguished civilian, Dr. Maine, a Member of the Supreme Council of India, and late Regius Professor of Civil Law at Cambridge, for his able treatise on "Ancient Law," a treatise which shows not only profound knowledge of the most abstruse principles of law, but the power of treating his subject with a simplicity of style and clearness of expression which render this valuable work interesting even to non-professional readers. Prizes were also given to Mr. Birch for the best design, with working drawings, for improved dwellings for the working classes; to Dr. Van Holst and Sir Wm. Holmes for the discovery and first importation of a sufficient quantity for commercial purposes, of a substitute for gutta percha; to the Artist-Workmen who had successfully competed for the prizes offered for

the best specimens of work executed in their own time; and to the successful competitors for the educational prizes and certificates awarded by your examiners.

In my address of last year, when announcing the policy the Council proposed to adopt during the then coming Session, I stated that, in justice to the Council, it was impossible to indicate the policy of any one year without referring to that of preceding years, or without considering the obligations undertaken for future years. I then endeavoured to show how persistently the Society, from its foundation, had promoted the study of the Fine Arts, first among the higher classes; and then, as other institutions were established to carry out a similar purpose, the Society adapted its plans to other classes requiring the stimulus which the publicity of the proceedings of a Society like ours affords. I also showed that we had steadily endeavoured to encourage the education of the industrial classes by the adoption of a system of competitive examination among the members of a large number of Mechanics' and other Educational Institutes in all parts of the country, and that a large measure of success had attended those efforts.

I now propose to show that in the encouragement of Manufactures and Commerce, and in the education of the Art-Workman, we have discharged and hope to continue to discharge an equally important duty. From 1761, when the first Exhibition of New Inventions was held in this house, to the present time, rewards have been constantly offered with a view to promote both Manufactures and Commerce. Commerce the Society promoted by offering prizes for the collection and introduction of new raw materials from all parts of the world. This branch of its duties it has consistently followed to the present time, for prizes, as I have already stated, were given at the last annual meeting for the discovery and introduction to our manufactures of a substitute for Gutta Percha. Time would fail me to enumerate various other vegetable and mineral substances which have been discovered and introduced into this country through the agency of this Society. It is sufficient for my purpose this evening broadly to state the fact, that Arts and Manufactures have been materially benefited by the stimulus the rewards offered by this Society has given to the discovery and importation of a large number of mineral and vegetable products. The Society also, for a great many years after its first establishment, allotted a considerable portion of its funds to the very important object of utilising waste lands by offering rewards, consisting either of the Society's medal or of money, for the purpose of encouraging the planting timber trees of all kinds according to the soils of the respective

districts. The number of trees thus planted, in consequence of the attention directed by the Society to this subject, must be numbered by millions: and no one can doubt the great benefit which has arisen from the value thus conferred upon this otherwise unproductive land. With regard to Manufactures, in the early stages of the Society many useful inventions were submitted to the Council in consequence of the rewards it offered: but the conditions necessarily imposed upon inventors who claimed such rewards that their inventions should become public property, precluded those who believed their inventions to be valuable from applying to the Society for its rewards: but in lieu thereof they appealed to the Patent Office for protection, whereby they hoped to secure the full pecuniary advantage to be derived from their discoveries. Still, notwithstanding this serious obstacle to the Society becoming the great vehicle for the communication of manufacturing improvements to the public, we find in looking through its Transactions, various suggestions and new ideas, which were ultimately improved and perfected, and led to many important discoveries. But of all the measures the Society has undertaken, none perhaps have been so successful and have so strongly proved its usefulness, as the encouragement it gave, in a very early period of its existence, to the exhibition of works of industry and new inventions. From the date of the first exhibition, in 1761 to 1849, the Society held periodically exhibitions of various kinds, which gradually prepared the way for the favourable reception by the public of the great idea of the International Exhibition held in 1851. From that time to the present exhibitions have been admitted to be most efficient means for conveying to the public a true idea of the progress and state of the Arts, Manufactures, and Commerce of almost every country; and the Council cannot but view with extreme satisfaction the general acceptance of this mode of registering the degrees of industrial progress. A reference to the Index in the last number of our *Journal*, just published, will illustrate my view of the popularity of Exhibitions more thoroughly than any simple statement, for we find that during the past year no less than forty exhibitions have been held in all parts of the world, with a view of exhibiting specimens of Art, of Manufactures, and of natural products. I will not trouble you with reading the names of the places where these exhibitions have been held, as you will find them in the Index of the *Journal* to which I have referred. With regard, therefore, to Manufactures, we must consider the Society rather as a body collecting and publishing new ideas than the absolute originator of great discoveries. But, whilst admitting this, I must claim for the Society

the great merit of being nearly the first to direct public attention to the necessity of improving the dwellings of agricultural and manufacturing labourers, and for inviting discussion in these rooms on many of the most important questions calculated to improve their social and mental position. No member of this Society will forget the great interest taken in this subject by our late President, the Prince Consort, who not only was President of the Labourer Friends' Society, but built at his own expense model cottages, as an example to all who interest themselves in the improvement of the social condition of the industrial classes. It is well worthy of remark that as far back as 1779 prizes were offered by this Society for improving the cottages of agricultural labourers; and on a great many occasions, from that time to the present, questions relating to the social condition of particular trades and the effect of strikes, both upon masters and men, have received constant attention by the Society. I allude to these subjects, which are every year increasing in interest, to show how slowly though how certainly all great questions relating to the social condition of the industrial population of this country have advanced in public estimation, till at length the time has arrived when scarcely any one can be found who will justify the present condition or sufficiency of the house accommodation of the great mass of the people.

At the beginning of this year the Society brought out a report on dwellings improvement in the metropolis, which contains, in a condensed and convenient form a large amount of useful data, together with indications of various points on which further information was desirable. Some of this information has since been supplied in the form of communications inserted in the *Journal*; and as regards dwellings reform on the continent, a comprehensive and valuable collection of documents has been received from a Privy Councillor of Bavaria, of which an English abstract is now in preparation.

Towards the close of last session the Society held a Conference to consider the best means of improving the dwellings of the labouring classes, which was well attended, and elicited a great deal of useful and practical information. The main questions brought under discussion were, the cost of new cottages, whether when built they would pay as an investment, and whether if built with proper and decent accommodation, the labourer out of his ordinary wages could afford to pay a rent at all adequate to the cost. As a pure matter of financial investment, it was, I think, shown—and the practical experience of all who have thought on the subject coincides with this view—that no one would be likely to make any serious investment in cottage building; but to landowners and agri-

culturists this is but one part of the question, and perhaps the smallest, for if four or even three per cent. upon the capital invested could be realised, and the labourer thereby provided with decent and healthy accommodation close to his work, there can be no doubt that, besides the return upon the capital embarked in building, received as rent, they would obtain a very large increase in the quantity of work done by each labourer, an increase the value of which it would be difficult to measure in money, but equal to the toil now expended in walking, in all weathers, long distances to and from the place where he is employed, and to the improved health and consequent increased vigour of body which would certainly follow his living in a well-ventilated, well-drained cottage, close to his work. The question of improving the dwellings of the working classes cannot be considered simply as one of cost and wages, for it is quite impossible that improved dwellings to any great extent can be erected by the occupiers of the soil unless they hold their land on such terms that they are certain of obtaining an adequate return for the capital invested. I cannot this evening enter into the numerous questions involved in the consideration of this great subject. I will merely express my hope that the enlarged views with regard to leases, which have been recently expressed by Lord Stanley and others, will ere long so improve the tenure upon which a great proportion of the farms of this country are now held, that every landowner and occupier will find it to be his interest, in a social and pecuniary point of view, to provide proper house accommodation for the labourers on his estate. At the Conference, whilst a great deal of time was devoted to the consideration of the cost for which a new cottage could be built, attention was not I think sufficiently directed to the cheapness with which existing cottages might be enlarged, their drainage and water supply improved, and thus to a great extent rendered both healthy and commodious. I hope that this part of the subject at any future discussion will be fully considered, for it appears to me that by this means great improvements may be made at a comparatively small expenditure, whilst the idea even of the outlay required to build new cottages for the labourers on an estate deters many from giving the subject all the attention it requires. Such was the sympathy excited by the Conference to which I have referred, that the Council resolved to appoint a committee, consisting of gentlemen known to take an interest in this inquiry, and possessing practical knowledge of its details, to consider and report upon the great variety of questions which, in the opinion of the Council, tend to retard the improvement of the dwellings of the working

classes. The Council hope that the appointment of this committee will be of considerable service by placing this subject in a practical form before capitalists, landowners, and all interested in the welfare of the community at large, and will assist in removing an evil of great magnitude, the continued existence of which is a disgrace to our country, and most injurious to the welfare of the people; indeed it is hardly possible to understand the apathy that has existed in the minds of the middle and the upper classes upon this subject. It must be so thoroughly the interest of all to cultivate the moral feelings of the industrious classes, that it would appear to be almost one of the first and most essential conditions of employing labourers to provide them with suitable habitations. To preserve their health and that of their families would also appear to be not only the duty, but the interest, of landlords and manufacturers. Men of feeling ought to do this on principle, men without feeling from motives of self-interest. When we recollect that it is from those inhabiting the wretched accommodation in which a large portion of our poor reside that we take our domestic servants, in whom we place so much confidence, and who are so necessary to our comfort, it is difficult to estimate the advantages which would be derived by the public from the improvement in their characters and conduct which would follow their being removed from the over-crowded habitations in which they are now brought up. Indeed I believe there is no more baneful source of intemperance among working men and sickness among their families than is produced by their living in badly-ventilated and ill-drained houses, the atmosphere of which produces that lassitude and debility which they attempt to remove by resorting to spirituous liquors. In every point of view, then, whether of principle or interest, this subject deserves the utmost attention of the community at large. I cannot dismiss this subject without adverting to the present state of the laws affecting the relief and removal of the poor, which it may be hoped will be so far ameliorated as to diminish the objections which now prevail against the providing residences for the poor in the districts where they labour.

In connection with the progress of our manufactures and the prosperity of the working classes, the Society has also given its attention to the question of strikes—a question of almost equal importance to that which we have just considered. Strikes,—the existence of which in the aggravated form lately exhibited in Staffordshire, notwithstanding the great improvement which has taken place in the education of the people,—prove that something is still wanting to afford them individually and collectively a true knowledge of their own interests. This subject will,

I hope, he again brought before the Society during the coming Session. It appears to me that the legislation of the last two years, with regard to commercial and manufacturing companies, opens to working men an entirely new relationship to their employers, which requires much consideration and the special attention of those who direct the education of their children. The large number of industrial establishments hitherto entirely under the control of individuals, but which have recently been formed into Joint Stock Companies, with limited liability, will I hope be the means of gradually preventing the recurrence of those differences between the employers and the employed, which have been prolific in causing mischievous combinations of workmen, and led them to follow the dictum of self-constituted committees, whose object appears to be the attainment of irresponsible authority over their fellow-workmen, rather than the real and permanent welfare of the class to which they pretend to belong. Hitherto the workmen have seen their employers accumulate vast capital, increase and extend their works, and live in almost princely style, upon profits derived in a great degree from their constant toil, and the intelligent exercise of their labour, whilst their own position, from the day they commenced life to their maturer years, has scarcely been improved. They still live in the same ill-ventilated, incommodious, ill-drained houses, in which it is almost impossible for them to maintain their families in health or decency; and perhaps, with the exception of obtaining better education for their children than they could get themselves when children, they are relatively in a worse social condition than their fathers were before them. Such facts, apparent to all, afford to the demagogue ample means and opportunity of exciting feelings of jealousy and distrust between workmen and their employers. Rightly or wrongly they look at the one practical result, that the employers of labour year by year improve their social condition, whilst they see no prospect whatever of any similar advantage being enjoyed by themselves. Under the law of 1862, the great manufacturing and trading companies recently organized must prepare properly authenticated balance-sheets, and thereby enable the workmen to know the exact result of their labour to their employers. Should these results be highly remunerative, and large profits be realized by the union of the capital and intelligence of the master and the skilled labour of the men employed, it will, I think, be difficult for the directors of such companies to avoid considering in what manner they can distribute amongst all connected with such establishments some proportion of the profits obtained. At all events it will afford fair ground and ample

knowledge upon which the workmen can press their claims before the directors, who, if they cannot meet them by reason and sound argument, will subject themselves to an amount of disaffection among their men which must ultimately end in the workmen endeavouring to enforce their reasonable requests by declining to work for such employers.

With a view to improve the Art education of working men and to encourage them in the course of self-improvement, the Council last year offered prizes for works of art executed by working men in their leisure time, from drawings and models furnished by the Society. The number of competitors for these prizes was 70, and it was to those who obtained, by the excellency of their work, the rewards offered by the Society, that His Royal Highness the Prince of Wales distributed the prizes at the annual meeting. The success of this attempt to encourage the cultivation of taste and skill was so satisfactory that the Society has published a much more extensive list of prizes, mostly of a higher character than those offered in 1863, to be competed for this year. The Council cannot but believe that the interest they have shown in everything relating to art workmanship has been very instrumental in originating the exhibitions supported by working men themselves which have recently taken place. The first, held in Lambeth, has been followed by one on a much larger scale in the North of London, and each of these exhibitions has in various ways received the support of your Society.

The Council wish, however, to suggest to the great Companies of this City, as well as of the municipal bodies in the country, the great benefits which must follow their occasionally combining to exhibit to the working classes the precious specimens of High Art Workmanship which many of them possess. To a workman, the knowledge that a particular work of Art can be produced, especially if he can see and examine it, is sufficient to stimulate him to attempt a work of Art of equal merit, and perhaps to excel it.

The Executive Committee of the Dublin International Exhibition, to be held next year, have formed a Committee of Advice, consisting of members of this Society and others, which is to meet in London, and the Council have given their consent to the meetings of the Committee being held in this house, hoping thereby to contribute to the success of the exhibition. At the same time, the Council have expressly stated to the Executive Committee that this Society would not incur any pecuniary responsibility in connection with such Exhibition.

Since we last met it is generally understood that the Royal Commission appointed to con-

sider the operation of the Patent Laws has made its report, but their report, although copies have been obtained by a few individuals, has not yet been issued to the public. I do not think it necessary, under these circumstances, to refer to the subject further, as no doubt, during the coming Session, when the report is published, it will be brought under the consideration of the Society at one of our weekly meetings.

The success of the Cantor Lectures last year has encouraged the Council to provide another series of three courses of lectures, to be delivered by Dr. F. C. Calvert, "On the Application of Chemistry to the Arts;" by Mr. Waterhouse Hawkins; "On the Relation of Science and Art to Manufactures;" and by Professor Ansted, "On the Application of Geology to Arts and Manufactures." Last year, uncertain of what the attendance might be, the Council issued tickets for the admission of two friends by each member; but owing to the number of members who were precluded, by the crowded state of the room, from attending these lectures, the Council, this season, must limit the issue of tickets to one for each member. Programmes of these lectures, and the days on which they will be delivered, will be duly announced in the *Journal*.

Having thus traced the progress of this Society almost since its first establishment, in its endeavours to promote improvements in our Manufactures and the extension of our Commerce, I will now endeavour, in conformity with the bye-law, to place before you the policy the Council intend to pursue during the coming Session. Continuing the measures we have taken to promote the education of Art-Workmen, we hope by extending the sphere of our operations and offering a greater encouragement to compete for the prizes the Society will offer, to produce greater results than have hitherto been attained in that direction. By the continuance of the Cantor Lectures we hope to afford to our members and their friends the means of obtaining the best and latest information on the subjects to which they relate.

The Wednesday evening Meetings will be continued as usual, and the Council hope that the members of the Society will assist them in making them as interesting as possible, by communicating the results of any new discoveries or processes, in papers, to be read at these meetings; and they are glad to announce that the season will be opened by a paper on the "Application of Iron to the purposes of War and Naval Construction," by Wm. Fairbairn, Esq., LL.D., F.R.S.

It will interest the members to hear that Mr. F. A. Paget, who read a paper in May last on "The Testing of Chain Cables," has, in consequence of the knowledge he displayed in that

paper, been requested, by the Board of Trade, in conjunction with Sir Wm. Armstrong, Mr. Wm. Fairbairn, Mr John Hicks, Mr. J. Nasmyth, and Mr. J. Penn, to report on the rules and regulations to be adopted by the Government in reference to the manner in which the testing operations, as directed by Mr. Laird's Act last session, shall be conducted.

Through the inquiries of the Committee appointed to consider how the difficulties which now appear to retard the provision of proper dwellings for the working classes may be overcome, we trust we shall be able to suggest measures by which this great plague-spot in the social condition of the mass of the people of this country may be materially mitigated if not removed. No subject can be more worthy the attention of the Society.

And continuing to investigate the causes of strikes, in connection with the altered state of the law of partnership, the Council hope still further to promote the harmonious working of that vast power which is wielded by the industrious classes of the kingdom, and which, if directed by sound principles, must tend very much to promote the prosperity of the manufacturers of this country.

It is specially a duty of this Society to persevere in this inquiry, now that some persons are doubtful as to the beneficial results of education amongst the working classes, attributing to it the greater power of mischievous combination, instead of considering in what respect the present education is imperfect, and the means whereby it may be more strictly adapted to the wants and special necessities of the industrial classes.

It is not customary I believe in these addresses to allude to public works, but those now in progress are of so much importance, and calculated in so high a degree to promote the objects the Society has in view, that I cannot avoid referring to them. The system of main-drainage, being carried out under the superintendence and according to the plans of Mr. Bazalgette, is a work worthy of the greatest city in the world, and no one can doubt that it will materially improve the sanitary condition of this metropolis; but, perfect as this system appears to be, it will be deficient in one great element of success if the refuse matter conveyed through its channels be not turned to some useful and profitable account. I hope we may have papers read at our evening meetings on this interesting and important subject, for it is one which ought to engage the attention of the mechanical engineer, the practical manufacturing chemist, and the agriculturist. And alluding to the drainage of London leads me to say a few words on the drainage and water supply of country towns and rural districts.

In a sanitary point of view this is of equal importance to the drainage of London; for, although there are not the same number of people crowded on a given surface, the want of proper drainage contaminates the water usually drawn from shallow wells, and produces most serious effects upon the health of the people.

The second public work to which I will refer, the Thames embankment, though of a totally different character, will produce results of almost equal utility and advantage, but this work differs in one respect from the main-drainage works, inasmuch as it will afford opportunities for the introduction of taste and ornament in its design, and will form one of the greatest attractions of this metropolis. The Thames embankment must be considered as the first great public work undertaken with a view as well to the embellishment, as for the improvement in the communication between distant parts, of this great city. It is rare, indeed, that it devolves upon one man to execute two such works, and to distinguish himself by the skill with which he has overcome the difficulties incidental to carrying out the system of drainage of a large city, and to exhibit so much taste and constructive skill as he has displayed in his designs for the embankment. Both of these works deserve the special notice of our Society during their progress toward completion, and I hope we shall find members willing to bring them before us, and to do justice to their respective merits.

Our underground railways, although conducted by public companies for individual advantage, may, from their great extent and importance, be considered as public works. I am more particularly induced to notice them, as they appear to be defective in one or two respects, which will offer good subjects for papers to be read at our meetings. The motive-power now used, and the ventilation required to remove the products of combustion incidental to the use of this motive-power, afford a fine field for the display of the ingenuity of the mechanical engineer. Perhaps it may be bold to recommend the introduction of the atmospheric system, which is associated in the public mind with most expensive failures, though on consideration it will perhaps be found that the causes which produced these failures do not exist in an underground railway. It was generally understood to be impossible to make a luting which would be equally effective in maintaining the partial vacuum required in the hottest day of summer and the coldest day in winter, involving as it does a variation of 60° to 80° of temperature often within a few hours; but in the underground railways, the temperature in summer and winter varies but little—certainly not sufficiently to destroy the efficiency of a carefully-prepared luting. We hope that this sub-

ject will meet with the attention it deserves, for if found to be practicable, it would materially add to the comfort of travellers by this novel, and, in many respects, most advantageous mode of conveyance.

In concluding this address I must express the gratification of the Council, which will, I am sure, be shared by the members present, at the very eulogistic manner in which the exertions of the Society, in promoting education among the members of Mechanics' Institutes and other kindred bodies, by means of competitive Examinations, have been noticed by distinguished members of Parliament and others, when speaking during the last few months upon the various modes by which a good education can now be obtained by almost every class of society. There appears every reason to believe that the Certificates granted by our Examiners are highly valued, and assist those who attain them in their advancement in life. We have also every reason to be satisfied with the annual increase in the number of papers submitted to the Examiners, and with the steady improvement in the degree of information exhibited in the papers prepared by the competitors for prizes.

I hope it may not here be out of place to refer to the want of public recognition which exists in this country for the highest class of intelligence, when devoted to the improvement of the Arts and the extension of our Manufactures and Commerce. Recently, no doubt, the Government has conferred honours on a few distinguished merchants and manufacturers, but such honours, having had in almost every case something of a political character, have been deprived of their value as a public testimony to services rendered through a long series of years in aiding to build up that great fabric of Commerce and Manufactures of which we are so justly proud, and upon the maintenance of which, in all parts of the world and among all nations, our national power and influence so much depends.

I am happy to congratulate the members on the continued prosperity of the Society, our numbers being larger than at the opening of any previous session; and the interest taken in the papers read at our evening meetings, shown by the numbers regularly attending them, proves that the policy hitherto pursued by your Council has been approved by the Society.

I trust that the statements I have been able to make this evening justify a confident anticipation of an equally successful progress during the session I have now the satisfaction to open.

After the delivery of this Address,

Vice-Chancellor Sir W. PAGE WOOD said he desired to submit to the meeting a resolution, which he was confident

would be received with acclamation, viz., a vote of thanks to the chairman for the very admirable address he had delivered. They had been accustomed to hear very able addresses from that chair. He would not make comparisons, but he would venture to say they had heard none more able than that with which they had been favoured that evening; and especially gratifying must the last announcement be, that the number of members of the Society was larger than at the opening of any former session; and when they looked back on the various subjects which had occupied the attention of the Society, as detailed in the address, the cause of this continued increase in the members was apparent. The Society had taken a great start from the period when it had adopted broader views in the promotion of Arts, Manufactures, and Commerce. The Society's rewards were bestowed with great care, and awarded to those who had done great services in promoting industrial progress and the welfare of mankind. When they saw that men of such eminence as Sir Rowland Hill and Dr. Maine felt themselves honoured in receiving the prizes of this Society, it was an evidence that it had risen in estimation, and was fully carrying out the important objects for which it was instituted. He considered this Society filled, with respect to Arts, Manufactures, and Commerce, the position which was occupied in commerce by the broker or agent. The broker ascertained and supplied the wants and needs of different classes of the community, and in like manner this Society received and diffused information for the benefit of those engaged in the several branches of science and industry to which its attention was directed. Such had always been the function of the Society, and it had of late years greatly increased its usefulness by adopting two special modes, which, though apparently different, were in reality based upon the same principle, the one stimulating the talent and skill of the younger branches of the community, and the other that of those more advanced in life and position. The examinations established by the Society accomplished the one; and on the other hand exhibitions might be regarded as competitive examinations for those engaged in industrial pursuits, in which men produced the best examples of their skill and placed them in competition with the whole manufactures of the world. Such was, he apprehended, the position which this Society was now taking; and how large were the sympathies of the Society in this matter had been admirably shown by the varied characters and position of the members whose deaths had been noticed by the chairman. They found mention of one man distinguished in the fine arts as a painter; they had lost another member noted in the walks of literature; and others in the mechanical art. The whole list of the Society, indeed, showed how men, distinguished in various walks of life, each devoted to his own pursuit, yet worked together, exercising the powers with which they had been gifted by their Maker for promoting the social happiness, the social comfort, and the social advancement of their fellow-men. He trusted that the very able remarks of the chairman with reference to the dwellings of the working classes would not be lost upon any present. This was a subject worthy of the utmost consideration in connection with a class of the community to whom they were so much indebted—men upon whose labour, and industry, integrity, sobriety, and morality, depended the whole constitution and fabric of the state; for he did not hesitate to say, if they had a corrupted working class, there could never be a great country or a great nation. It was a source of satisfaction to know that they had a working class which he might say, with some knowledge of the workmen of other countries, stood in a high and distinguished position with reference not only to industry—for that was known to the whole world—but in morality and integrity. Where there were defects, they might be traced to the miserable condition of the habitations in which so many were compelled to live. The railways, whilst

they had driven vast multitudes of the working classes from their former habitations, promised to do much in the way of remedying this evil. They had heard on former occasions of plans devised, not only from motives of benevolence, but upon the soundest principles of political economy, for conveying the working classes at cheap rates, not only from one part of the metropolis to another, but to localities where suitable habitations were provided at rents within their means. The chairman that evening had made reference to other plans, into the details of which it was not his province to enter. The chairman had stated, to his (Sir W. P. Wood's) surprise, that some copies of the Report of the Commission appointed to consider the working of the Patent Laws had got abroad. Now, as he happened to be one of the commissioners, and as he had not yet signed the report, he was at a loss to understand how any copies of it had got abroad. It was no doubt a subject of great importance to all interested in it, but he might say, as had already been stated by the chairman of that commission (Lord Stanley), that he was afraid it might much disappoint those who expected great results from it. He drew attention to the several topics in the Address, because he felt that, to the wide range of subjects which occupied their attention, was mainly due its increasing numbers and its means of usefulness; and while the Society continued to be guided by the principles on which it had been governed for several years past, and for the introduction of which, it must be recollected, they were largely indebted to the personal interest of the late Prince Consort, future chairmen would report its continued prosperity. He begged, in conclusion, to ask the members of the Society to tender to the chairman their best thanks for the able address he had given them.

Mr. JOHN DILLON seconded the motion.

Mr. HARTLEY, as a manufacturer and large employer of labour, called attention to the great scarcity of skilled labour in this country, which he said was the case to such an extent that a very large amount of skilled workmanship had to be sent abroad to be executed. This was a subject which he hoped would be taken up by the Society. There were abundant means of supplying the requisite amount of skilled labour which an increasing trade demanded; and the advantage to a boy being properly educated as a skilled workman was equal to giving him £600.

Mr. P. PALMER expressed a hope that the influence of the Society and of the Chairman, as a member of one of the principal City companies, would be exerted to induce those corporations to exhibit the rich treasures of works of art which they possessed for the benefit of the community. He thought it would well comport with the position and dignity of the great City companies to co-operate with the Society in the way he suggested in aiding the spread of the art education of the country.

Mr. HARRY CHESTER might so far answer, on behalf of the Council, the observations just made by stating that the question of skilled labour was one which had largely engaged the attention of that body. They were aware of the great want that existed. They were not, however, at present prepared with any particular plan from which they hoped to derive any great results in that direction; but it was a subject which in various forms had been always more or less before them. The exhibitions which had been suggested by the last speaker might have a tendency in that direction, and it would be most gratifying to the Council to give their aid to any scheme which promised to be instrumental in carrying out the extension of their object.

The resolution having been put was carried by acclamation.

The CHAIRMAN acknowledged the high compliment which had been paid him.

The SECRETARY called attention to some very fine

photographic enlargements from small negatives, executed by means of Dr. Van Monkhoven's improved solar camera, and lent by Mr. J. H. Dalmeyer.

Proceedings of Institutions.

FARNHAM YOUNG MEN'S ASSOCIATION.—On Friday evening, November 4th, the lecture session of 1864-5 was opened with the delivery of a lecture, by the Rev. J. McConnel Hussey, of Brixton, on "Home." The Bishop of Winchester, president of the association, occupied the chair, and in introducing the lecturer congratulated the members on the advancing prosperity of the association, and gave particulars in reference to the past lecture session, the working of the library, and reading room.

LONDON MECHANICS' INSTITUTION.—On Friday evening, the 4th of November, a distribution of the prizes and certificates obtained by the members of the Institution at the last Examination of the Society of Arts; also at the Examination of the Metropolitan Association for Promoting the Education of Adults; and also the prizes offered to the classes by the Local Board of the Institution, took place at the London Mechanics' Institution, Southampton-buildings, Chancery-lane. The prizes consisted of standard popular works, in handsome bindings. Mr. HARRY CHESTER presided, and the Honorary Secretary of the Local Board of Examiners stated that the candidates examined this year, while obtaining a fair share of honour for themselves, had not failed to maintain the reputation of the Institution. Eighteen candidates presented themselves to the Board for the Preliminary Examination required by the Society of Arts, of whom sixteen were passed for the Final Examination by the Society's own Examiners. Of these, fourteen attended, and obtained between them (none having been rejected) twenty-seven certificates—nine first-class, fifteen second, and three third—with the first and second prizes in logic, the second prize in English history, and the third in English literature. A number of the junior and less advanced members of the Institution had availed themselves of the Examinations of the Metropolitan Association for Promoting the Education of Adults, which, like those of the Society of Arts, were conducted by the Local Board, but were of a more elementary character. The candidates obtained a fair proportion of certificates, and several of the principal prizes offered by the Association. A Competitive Examination of the classes of the Institution had been held by the Local Board, and book prizes awarded to the successful candidates. Mr. Reed appealed to the members for donations to the prize fund, in the shape of books or money, and as an instance of the successful working of the Board, stated that during the past five years only one candidate passed by them for the Examination of the Society of Arts had been rejected. The Chairman, with a brief explanation of the nature and working of the Examinations, proceeded to distribute the certificates and prizes, at the same time announcing that Her Royal Highness the Princess of Wales had given a prize of a Bible, value three guineas, to be contended for in needlework by young women. Her Royal Highness's name would be written by her own hand in the Bible. The prizes having been distributed, the chairman, in closing the proceedings, congratulated the meeting on the great success of this, the oldest of the Mechanics' Institutes. The City of London College, which was a much larger Institution, sent up a greater number of candidates, but for its size none had been more successful than the London Mechanics' Institution, nor had entered more heartily into the views of the Society of Arts. They had opened three classes to women, which he thought a great advantage. He did not approve of opening the Universities to females, but hoped that before long a suitable scheme would be

matured for the furtherance of female education. The proceedings terminated with a cordial vote of thanks to the chairman.

MARLBOROUGH READING AND MUTUAL IMPROVEMENT SOCIETY.—The twentieth annual report of the Society states that further accommodation has been made to the library, giving increased facilities in the selection of books. The Corn Exchange Committee have lent the Exchange for the opening and other lectures of the present season. In order to make the building available for lectures, an outlay of about £5 was absolutely necessary, and a further similar sum will be required if the building is continued to be used for all or the more popular of the Society's lectures.

THE CONDITION OF MINES IN GREAT BRITAIN.

The report of the commissioners* appointed by her Majesty to inquire into the condition of all mines in Great Britain to which the provisions of the Act 23 and 24 Vic., cap. 151, do not apply, with reference to the health and safety of persons employed in such mines, has just been issued. The report occupies upwards of forty pages of a small blue book.

From a careful consideration of the evidence they have heard, and of the reports and documents prepared in the course of the inquiry, and from the knowledge acquired by visiting the districts and by inspecting mines therein, the commissioners have agreed to the following resolutions:—

"1. That there is a great excess of sickness and mortality among metalliferous miners, which is mainly attributable to the imperfect ventilation of the mines. However diverse the opinions of medical men may be as to the causes of the disease called 'miner's asthma' or 'miner's consumption,' there is a remarkable concurrence among all the writers on the subject in this, that the health of the miner is greatly influenced by the quality of the air in which he works. The more extended inquiry instituted by us under the royal commission gives strength, if not certainty, to this conclusion. In the coal districts, where, on account of the dangerous gases, great attention has been given to the proper ventilation of the mines, the mortality (accidents excepted) among the miners is considerably less than it is in the metalliferous districts. We have on this account thought it advisable to make ourselves acquainted with the systems of ventilation usually adopted in coal mines, in the hopes that we might thereby be able to offer some suggestions for improving the ventilation in the metalliferous mines. The main object to be kept in view in ventilating a mine is to conduct a sufficient supply of pure air through the mine in order to displace the vitiated air where the men are at work. Various contrivances have been put in practice for effecting this, but they are all applications of two principles, propulsion and extraction; by the first pure air is forced in, by the second foul air is drawn out. The power used may be either natural or artificial. Natural force acts when columns of air are, in the absence of any artificial means, of unequal weight, in which case the heavier column displaces the lighter, and so causes movement and change of air. Another natural force acts when the wind blows in at a level or over a shaft. Artificial propulsion is effected by various applications of machinery and other contrivances, such as falling water, the water blast, or the fan; artificial extraction, by suction or by furnace heating. The most simple method of ventilation is by natural agencies directed and supplemented by engineering skill. Two or more shafts or adits are essential, so contrived that one shall be upcast in all states of the

* The Commissioners were—Lord Kinnsaird, Sir P. M. Grey Egerton, Nicholas Kendal, F. Leveson Gower, John St. Aubyn, R. Davey, E. Headlam Greenbow, and P. H. Holland, with J. F. Campbell, Secretary.

weather. A system of trunk ventilation being thus established the pure air may be guided to any part of the mine where it may be required, if care be taken to remove all refuse or 'deads,' and to close up all old and abandoned workings, by which the currents of air may be interfered with. In cases where natural ventilation is insufficient, artificial means must be resorted to, and of these it appears to us by far the most effectual, where it can be adopted, is that which is generally in use in the coal mines, namely, the rarification of the air in one of the shafts by the heat of a furnace. The mechanical means which have been suggested are the introduction of pure air by a force pump, and the abstraction of foul air by a suction pump. Machines for the latter purpose are in successful operation in some collieries and mines in this country. The foregoing remarks chiefly apply to the maintenance of a regular system of trunk ventilation. In small mines, and in certain parts of large mines, a good supply of air may be provided by means of contrivances which cannot be economically applied on a large scale, such as different descriptions of air pumps, water blasts, and fans. These may answer the purpose when judiciously applied and carefully attended to. It appears to us worthy of consideration whether some combination of natural with artificial appliances might not be adopted at a comparatively small expense, considering the benefit that would thence accrue both to the employer and employed. Cases have come before us of mines in which, in certain conditions of the atmosphere, the circulation of air underground is regular and sufficient, while at other times it varies both in quantity and direction, consequent upon the inversion or stagnation of the current of air in the shaft. This evil might be effectually conquered by the maintenance of a constant upcast shaft, and, where natural causes fail, this might be effected by an application of furnace heating. Whatever system, however, may hereafter be adopted, it is essentially necessary that attention should be paid to driving the levels of sufficient size, to making more frequent communications between them, to removing the refuse, closing up disused winzes, sumps, shafts, and abandoned workings, and to the judicious application of air-tight doors and brattices so as to control the direction of the underground currents.

"2. That several other causes, both general and local, largely contribute to impair the health of the miner—namely, exposure to cold and wet, and to sudden alternations of temperature; wearing wet clothes, inhalation of gritty particles; and the exertion of climbing ladders from great depths.—Amongst the causes enumerated by the medical men as tending to impair the health of the miner, exposure to sudden alternations of temperature to wet and cold is much insisted upon. The miner is peculiarly liable to these dangers, either from imprudence on his own part or from want of proper arrangements on the part of his employers. Another cause most injurious to the health of the miners is the exertion of climbing ladders continuously from great depths. The evidence of the medical witnesses and of the miners themselves leaves no doubts on our minds as to the pernicious effects of severe climbing upon men whose constitutions are, perhaps, impaired by the conditions under which they work, and the severity of the work itself. This evil is occasionally enhanced by the impure state of the air in the ladder ways, and aggravated by the indiscretion of the miners themselves, especially the younger ones, in mounting the ladders with too much haste. In those mines where the man engine has been in operation the improvement in the health of the miners is stated to be evident. In most coal mines workmen are conveyed up and down the shaft in the 'cages.' This arrangement appears to us to be expeditious and safe, when due attention is paid to the construction and supervision of the machinery; and we think it might be advantageously introduced in many of the metalliferous mines. We therefore recommend—1. That every mine should be

provided with proper houses conveniently situated, in which the men can change and dry their clothes. 2. That surface work should, as far as practicable, be carried on under shelter, and that suitable places should be provided in which women and children employed at the mines might take their meals. 3. That in order to avoid the evils consequent on climbing ladders, mechanical means should be provided to convey the men to and from the surface when the mines are of great depth.

"3. That accidents are of frequent occurrence in metalliferous mines, and that they principally result from miners falling from ladders and stemples, or from one level to another; from falls of the rock or stuff; from want of caution in blasting; from defective gear and imperfect supervision of machinery; from sudden irruptions of water or foul air, and from the bursting of boilers.—To obviate as far as possible the various accidents to which miners are exposed, we recommend,—1. That no ladderway should be allowed in a drawing shaft without the shaft being properly divided or bratticed off from the footway, and that efficient sollars should be fixed at moderate distances in all footways, whether the ascent or descent be by ladders or stemples. 2. That shafts, winzes, sumps, and shoots should be more carefully guarded. 3. That more stringent rules should be enforced in regard to blasting, with a view to preventing accidents, and that bronze tampering rods and pricklers should be supplied to the men. 4. That the persons having charge of the footways and other works underground should daily enter in a book a report of their condition to the agent or captain of the mine, which should be produced in case of inquiry. 5. That the boilers and other machinery should be periodically examined by the mine engineer, and that a monthly report thereon should be given in to the captain or agent, to be produced by him should occasion require. 6. That the men should not be allowed to change in the boiler house, which none but those in charge should be permitted to enter. 7. That all boilers should be provided with two safety valves and a water gauge or a steam whistle. 8. That plans and working sections of all mines on their being abandoned should be deposited at the office of the clerk of the peace for the county, and at the Government Mining Record Office in Jermyn-street, for reference in case of working being resumed, or new mines opened up in the immediate vicinity.

"4. That abandoned shafts, and old works unprotected at the surface, are a cause of serious danger, not only to the miner, but to the public.—The accidents consequent upon the practice of leaving abandoned shafts and works insufficiently guarded or wholly unprotected, are so numerous that we think it very desirable that an efficient and easily available legal remedy should be provided in order to guard the public from this prolific source of danger.

"5. That the employment of boys underground at an early age contributes to produce disease and premature death.—We therefore think it desirable that, as a general rule, no boys under the age of fourteen years should work below the surface.

"6. The system of mine clubs as at present in general operation is unsatisfactory, as not providing for cases of sickness as well as of accident.—We therefore suggest the adoption of such a system of mine clubs as would afford the men sufficient maintenance during sickness as well as while suffering from the effects of accident."

Manufactures.

SILK MANUFACTURES OF SWITZERLAND.—The export of silk goods in 1862 was 35,412 cwts., which was much more than any preceding year, than even 1859, which was considered a very favourable one. Most of the coloured silk stuffs are made, Bâle being chiefly celebrated for its ribbons. The newly-invented aniline dyes are rapidly taking the place of the figured silk for ribbons. Some

idea of the work done at the dyeing establishments can be formed, when it is stated that one, Mr. Clavil, of Bâle, turns out 90 cwt. of dyed silk per week, and pays away in expenses about £20,000 a-year. There are thirty-one ribbon manufactories at Bâle, and two for stuffs. By far the largest number of weavers are employed in their own houses. The proportion of looms is about 1,500 in factories and 6,000 dispersed in different parts of the country. The silk industry of Bâle may be considered as a vital occupation for the town. On this more than 10,000 persons, or a fourth part of the town population, subsist.

PAPER IN DENMARK is for the most part of very inferior quality; protected under the old tariff by a high import duty upon foreign manufacture, and an equally high export duty on rags. This manufacture is represented by 18 mills, only six of which are of any importance.

PREPARATION OF FLAX.—A French manufacturer, named Bertin, has invented what is reported to be a successful method of dispensing with the steeping of flax. After the fibres have been crushed in the ordinary way, M. Bertin submits them to a new process, that of friction between two channelled tables, which have a sideways as well as to-and-fro motion; in fact, the action is similar to that of rubbing the fibres between the palms of the hands, but under considerable pressure and with great rapidity. The fibre is afterwards beaten in water, which carries off every particle of woody matter and leaves the flax completely unbroken and in parallel masses. The principle of friction tables has been applied by M. Bertin in other cases, and is said to furnish an economical, rapid, and perfect mechanical action. The same gentleman has adopted a new system of chemical steeping to get rid of the resinous and other matter which attaches the fibres together, which is said to produce the required effect in less than two hours, at a cost of about 1s. 8d. per cwt., leaving the flax nearly white; but the particulars are not given. By M. Bertin's system it is affirmed that the yield of flax is raised from 12 or 15 to 20 or 22 per cent. of the gross material. Lastly, M. Bertin collects the refuse beneath his crushing machines, burns it in his boiler furnaces, and uses the ashes and the water in which the flax is steeped as manure, giving back, as he affirms, the whole of the mineral salts and azotised matter contained in the crop, and the cost of so much artificial manure saved to the cultivator.

DIS FIBRE.—The Jury of the Exhibition of 1862 awarded a medal to M. Lafon de Caudaval for his specimens of paper and yarns prepared from the plant called *Dis* by the Arabs, and by botanists, *Festuca patula*, *Arundo festuoides*, *Arundo mauritanica*, or *tenax*, and its claim to the attention of the commercial world is being prominently put forward in France. It is reported to grow spontaneously on the coast of Algeria, over an extent of 250 leagues, and is said to yield 84 per cent. of fibre, 6½ per cent. of gluten for use as tapioca, and 9½ per cent. of water and herbaceous elements. The fibre is applicable to the making of paper, coarse fabrics, and cordage, and is not subject to the attacks of insects. For paper making it is treated in the same manner as rags. For the extraction of the gluten the crushed plant is steeped for three or four days in lime water, and afterwards for the same period in an acidulated solution; this disengages carbonic acid gas, which, in escaping, exercises, apparently, a kind of mechanical action in completing the separation of the fibres, and these are afterwards beaten in water by machinery. The average length of the *Dis* fibre is given at nearly five feet, and the cost of the prepared flax at about 4s. 6d. per cwt.

Commerce.

PIRACY OF TRADE MARKS.—A deputation from the committee of the Association of Chambers of Commerce,

joined by delegates from the Birmingham, Sheffield, and Wolverhampton Chambers, had an interview on Friday, the 11th instant, with Mr. Layard, Under-Secretary of State for Foreign Affairs, in order to impress upon her Majesty's Government the injury to be apprehended from the provisions in reference to trade marks contained in the Franco-Prussian and Anglo-Prussian treaties of commerce. The deputation consisted of Mr. Sampson S. Lloyd, of Birmingham, chairman of the Association of Chambers of Commerce; Mr. Atkinson, Master Cutler, of Sheffield; Mr. Robert Jackson, president, and Mr. W. Smith, secretary of the Sheffield Chamber of Commerce; Mr. H. W. Ripley, president of the Bradford Chamber of Commerce; Mr. Robt. Fletcher, Mr. Yates, and Mr. Bartleet (Redditch), of the Birmingham Chamber; and Mr. Loveridge and Mr. E. J. Gibbs, of the Wolverhampton Chamber. The deputation pointed out in detail the dangerous effect of the second portion of the 28th article of the Franco-Prussian treaty, which legalises for ever the piracy of all trade-marks whose origin is anterior to their registration in the country of importation, whose registration could not take place until about two years ago. The injurious effect of the clause upon the interests of honest manufacturers in France itself was demonstrated; and the strongest testimony was borne by gentlemen from Sheffield, Birmingham, and Redditch, as to the ruinous results to be apprehended from its operation on the hardware manufactures of this country. Numerous specimens of German forgeries of the marks of eminent British makers, which are publicly sold in large quantities in various continental countries and in America, were shown. The deputation urged upon her Majesty's Government to make use of such facilities as they possess to represent to the French Government the injurious consequences of the clause, in order, if it be not too late, to obtain its modification in the Franco-Prussian treaty. It was also hoped that in any direct negotiation between Great Britain and the Zollverein a clause would be introduced providing for the efficient protection of all British trade marks; and failing that, the opinion was unanimously expressed that the treaty would be more valuable if the second clause of Article 28 were altogether expunged.

FRENCH IMPORT DUTY ON SILK RIBBONS.—The Liverpool Chamber of Commerce have received a communication on this subject from the Foreign-office, to the effect that, in virtue of the treaty lately concluded between France and the Swiss Confederation, the French import duty on silk ribbons has been reduced from 8s. to 4s. per kilogramme, a decrease of 50 per cent., the advantages of which will be shared by British industry as soon as the Franco-Swiss convention comes into operation.

COMMERCE OF JERUSALEM.—"Jerusalem," observes the British Consul in his annual report to the Foreign Office, "is the least commercial or industrial city I know. British trade is represented by one English tradesman, who keeps a store for English upholstery, drapery, and fancy goods. The population of the city is computed at 15,000, rather more than half of them Jews, the rest Molems and Christians. The chief native industry is the manufacture of soap and "Jerusalem ware," this latter consisting of chaplets, crucifixes, beads, crosses, and the like, made for the most part at Bethlehem, and sold to the pilgrims, who annually flock to the holy city to the number of about 6,000. The population of the entire Sandjak, or province, is estimated at 200,000, of whom 160,000 are Mahomedans. Owing to the absence of good roads and the insecurity arising from the predatory tribes of Bedouins inhabiting the outskirts of the district, but who could easily be kept in check, vast and fertile plains lie waste or are but partially and poorly cultivated; factories are not to be met with, and no mines are worked, though it is believed that sulphur, bitumen, and rock salt abound on the shores of the Dead Sea. The principal, if not the only imports from England are cotton goods, and some colonials, but the former have much diminished since the cotton crisis; it is calculated

that 300 bales of these goods, of the value of £16,000, annually find their way here. The exports are olive oil and grain. Very little is done in cotton culture, what is raised being of inferior quality, and consumed on the spot; but it is believed that in many parts of the country cotton to a large extent might be successfully cultivated, with good seed and proper instruction and implements given to the peasantry. The vegetable produce is barely sufficient for local requirements. Jaffa is the port through which Jerusalem deals with foreign countries. The trade of Jaffa experienced a considerable increase in 1863. The quantity of cotton exported rose from 55,000lbs. in 1862 to nearly ten times the amount in 1863, with a prospect of this being trebled or quadrupled in 1864. This was owing to the interest exercised. The merchants who operated in cotton made a profit of about 25 per cent. There are regular lines of French, Austrian, and Russian steamers, all doing well, and very often large quantities of goods have to be left behind for want of room; but only one English steamer visited Jaffa in 1863. The exports exceeded £200,000; of the imports no statistics are kept. The consul reports a telegraphic line in course of formation by the Government between Beyrout and Jaffa, thence to be carried on to Alexandria.

Colonies.

VICTORIA.—The Border Customs question has assumed an aspect which promises some trouble to the Governments of Victoria and New South Wales, and some inconvenience to the inhabitants of the Riverine district and the merchants who trade with them. The Murray River Railway will be finished in the course of three or four weeks. Echuca, the township on the Victorian side of the river, will then become the port for the trade of the vast plains which stretch northwards to Cooper's Creek, watered by the Lachlan, the Murrumbidgee, the Warrigo, and other rivers. These plains, however, are within the limits of New South Wales and Queensland, and as the tariff of Victoria is much more liberal than that of New South Wales, the Sydney Government proposes that the Victorian authorities should collect the extra duties on goods sent across the Murray from this colony, handing the amount over to the Treasurer of New South Wales, on payment of a commission for collection. This course the Victorian Government refuses to take, requiring, it is understood, some concessions as to the navigation of the Murray. In the meantime some half dozen customs' officers have been stationed at points on the northern bank of the river, with instructions to seize all goods coming from Victoria on which the New South Wales tariff charges have not been paid. The question has been embarrassed by the fact that a wrong has been committed on Victoria, when her boundaries were fixed, in some manner never yet satisfactorily explained. When separation was proposed the river Murrumbidgee was named as the northern boundary of this colony. A dispatch from Lord John Russell shows clearly that the Home Office assented to that line; but when separation was accomplished, it was discovered that the southern bank of the Murray had been substituted for the Murrumbidgee. As neither government is likely to give way in this matter, and the protective principles which find favour in Sydney are opposed to the views entertained in this colony, and there is no probability of the tariffs being assimilated, the course which has been taken therefore is likely to lead to smuggling to a large extent, and the creation of a class of borderers who, in this respect at least, may rival those of the Tweed and the Solway. In commercial matters the state of the colony is sound.

ROYAL SOCIETY OF TASMANIA.—The monthly meeting of this Society was held at Hobart Town on the 9th August, but the proceedings have only just been published. A number of returns were laid on the table, together with

several presentations. Mr. M. Alport having reported that the salmon and trout in the breeding ponds were proceeding in a perfectly satisfactory manner, read a paper on the food for salmon in the Tasmanian seas and rivers. Mr. Gould exhibited a map, geologically coloured, of a part of the county of Dorset, and gave a brief description of the distribution and extent of the more important formations. He commented on the absence of the carboniferous and the abundance of granite and older palaeozoic rocks. In speaking of the expansions of semi-waste low land, bordering on the coast, he referred to a tufaceous limestone which crops out in thin ledges along the same bank which forms part of the tertiary deposits at Table Cape and Macquarie Harbour, and cited them as showing that the recent elevation of the island had been greater upon the northern than upon the southern side. After pointing out the courses of the more important ranges, he gave a short account of the fertile basaltic areas of Scott's country; he also alluded to the efforts that have been made to discover gold at Nine Mile Springs, and the Devil's Den, referring more especially to the latter as exhibiting gullies of some promise, and pointing out that the work hitherto performed had been perfectly insufficient to afford any test as to the existence of gold, only a few men being employed, and the work performed by them having been in part ineffective, from an injudicious selection of the spot tried.

SOUTH AUSTRALIAN REVENUE.—The *S. A. Advertiser*, of the 26th of August, 1864, says:—The revenue for the year ending June the 30th, was £693,840; the expenditure £600,666; the colonial bonded debt, £840,000. The imports for the last quarter amounted to £882,762; for consumption in the colony, £610,160; the total exports of south Australian produce for the same quarter, £670,018.

REVALUATION OF AUSTRALIAN LAND.—The great question of the day, and one that almost totally excludes all other business, is that of the revaluation of the runs, the leases of which expire in 1865. About 200 of these leases will then fall in, and as the valuator has increased the rental of the first eighteen about sevenfold, the squatters have taken alarm. But even this enormous increase will leave the lessees in possession of the finest grass lands of the province at 6d. per annum per acre. By the 10th of September all the runs situated in the northern parts of the province of South Australia, about eighty in number, will be revalued. There has been no such struggle for many years.

WINE.—California will make 1,500,000 gallons of wine this year.

COCHINEAL IN AUSTRALIA.—At a meeting of the Acclimatisation Society of New South Wales, held in August, 1864, Mr. Moon announced that the cochineal insect had at last reached the colony alive. For many years past he had used every effort towards obtaining this object, but until then without success. He had had the insect sent to him from America, Madeira, and England, but it had in each instance perished before it had arrived. The society is now indebted, for the introduction of this valuable insect into the colony, to Sir George Grey, Governor of New Zealand. The insect feeds upon the *Cactus opuntia*, and, as a matter of course, the cacti without spines, of which there are several species in the colony, are the most useful.

Obituary.

HUDSON GURNEY.—On Wednesday, the 9th of November, died Hudson Gurney, of Keswick, near Norwich. His life was protracted beyond the usual space allotted to man. When he was born, Joseph the Second had not long ascended the Austrian throne, nor had Frederick the Great made that journey into Silesia which brought about his end, and the female Tiberius, Catherine, consoled her-

self for the loss of Lanskoj by her secret marriage with Potemkin, and her selection of the subaltern Yermoloff. Arrived at manhood, Mr. Gurney assumed the position he may be said almost to have inherited, and added to that position by his intellectual qualifications, which gave him the right of association with Byron and Coleridge, Shelley and Keats, Wordsworth and Southey, Scott and Hook. The subject of this notice was born in the year 1785, and, had he lived till January next, he would have reached the great age of 90. He was a ripe scholar, and possibly the best read man in Norfolk. At an early age he obtained a seat in Parliament, and originally sat for the Rape of Bramber, Sussex, and afterwards was M.P. for Newport, in the Isle of Wight. A serious illness brought about a change of ideas, and Mr. Gurney resigned his seat in the House of Commons, and settled down into the quiet charms of domestic life. His income was reputed to be enormous; but, enormous as it was, his charities kept ample pace with its receipt. He appeared to live only with the one idea, and that was, the doing good. He was a patron of art and an elegant and accomplished scholar. It is asserted, and it is believed with much truth, that he expended upon charity as much as £10,000 per annum. There are many men who possess as great qualities as Mr. Hudson Gurney, many who have performed greater actions; but few like himself, reared in the lap of fortune, have ever so persistently and perseveringly entered into the affairs of the poor, and so instinctively, as it were, identified their interest with his own. For many years he had retired from public life. His habits were somewhat singular, since he sat up writing or reading, it is said, through the entire night, generally retiring to bed at daybreak. It is stated that several valuable works from his pen lie on the bookshelves at Keswick Hall; and it is hoped, now that the author is no more, they will be given to the world. The little that is known of the literary capabilities of Mr. Hudson Gurney shows him a man of great intellect; and his translation of the "Cupid and Psyche" of Apuleius is a sufficient proof of the stuff that was in him.

THE DEATH OF MR. J. R. M'CULLOCH, on the 11th of November, is the loss of a valuable public servant and a distinguished man of letters. He had been for some time past subject to attacks on the chest of a dangerous tendency, and his last seizure a few days since proved fatal. From its commencement he gradually declined in strength, but retained all his faculties till his last moments. Mr. M'Culloch was born in Wigtownshire, on the 1st of March, 1789, and he was, therefore, in his 76th year. His father possessed a small freehold estate in that county, and was of the class of small proprietors in the English border counties denominated "statesmen"—cultivators of their own acres. The son received from his maternal grandfather, a Scotch minister, his early education; that is, he was "grounded" in his mother tongue, with some elementary instruction in the dead languages after the then Scotch fashion. On leaving school Mr. M'Culloch was placed in the office of a writer to the signet, but he did not pursue the profession of the law. He settled in Edinburgh and attended the public classes of the University for two years, but did not graduate or study for any profession. Early in 1817 an accidental communication of Mr. M'Culloch's to the *Scotsman* (then first established) led to his connexion with that journal, and for some time he was the editor. In the following year he commenced a series of contributions to the *Edinburgh Review*, and also gave lectures on political economy. In 1820 Mr. M'Culloch quitted Edinburgh for London, continuing his contributions to the *Scotsman* for some years, but contributing also to other periodical works and giving lectures on political economy. In 1828 he was appointed professor of that science in University College, London; but, the chair being unendowed, the number of students attending his lectures was insufficient for his remuneration, and he resigned the professorship. In 1838

the Government appointed him Controller of the London Stationery-office, at a salary of £1,000 per annum, and he continued the head of this department till his death. When he undertook its administration the Stationery-office was an Augean stable. The long and habitual waste of paper in the consumption of the public offices and in printing was fabulous. Mr. M'Culloch accomplished a large annual saving, far exceeding the cost of the department he presided over. By his stern economy and hatred of "jobs" he of course created enemies; but his judicious savings and integrity were undisputed, and are matters of record in Parliamentary reports and returns. Mr. M'Culloch's more lasting and meritorious reputation, however, was gained by his literary labours. They were the result of forty years of study and experience. Statesmen had attended his lectures in London, and his contributions to periodical works had been various and diffuse. But he now began to realize his acquirements. In 1837 Mr. Charles Knight published, in two 8vo. volumes, his *Statistical Account of the British Empire*. This valuable work was subsequently republished by Messrs. Longman in successive editions much enlarged. The latter publishers brought out his *Dictionary of Commerce and Commercial Navigation*—a standard work annually reprinted and revised. These two works may be considered his staple productions, and they were reprinted in the United States and translated in several European countries. His miscellaneous works were numerous, and all more or less valuable contributions to political and economical science. In 1828 he edited for Messrs. Longman, in four vols. 8vo., the best edition of Smith's *Wealth of Nations*, with a life of the author, an introductory discourse, notes, and supplementary dissertations. In 1853 he published a volume of *Treatises and Essays on Economical Policy*, comprising sketches of Quesnay, Adam Smith, and Ricardo. This work was partly a republication of articles contributed by the author to the *Encyclopædia Britannica*, but all were carefully revised and in part re-written, some essays appearing for the first time. In the same year appeared his volume on the *Principles of Political Economy*, lastly corrected and revised. In 1855 he published his treatise on the *Principles and Practical Influence of Taxation and the Funding System*. In 1858 he also published a valuable work on the "Succession to Property vacant by Death; including inquiries into the influence of primogeniture, entails, and compulsory partition upon the public interests." Mr. M'Culloch collected a library on his own special subjects of great value. It contained not only almost every known English word on political economy and statistics, but every foreign publication on those subjects, and it comprised every pamphlet, known or anonymous. In 1855 he published a bibliographical volume on the literature of political economy, a catalogue of his best books, with historical, critical, and biographical notices; and only two years since he completed and privately printed a more extended and valuable catalogue *raisonné*. Of the latter volume a very few copies were presented to personal and literary friends. The motto on the title-page of this volume was from Barrow:—"The reading of books, what is it but conversing with the wisest men of all ages and all countries, who thereby communicate to us their most deliberate thoughts, choicest notions, and best inventions, couched in good expression, and digested in exact method?" The genius of Mr. M'Culloch was not inventive. He sifted and re-cast the labours of others. Statistics, rather than the principles of political economy, were his forte; but his works were generally lucid and sound. He occasionally indulged in paradox; but in this error he only followed Malthus, Whately, and Senior. There are unsolved problems in political science; and men of genius in advance of their generation, groping in the dark, must sometimes lose their way. Mr. M'Culloch was an original member of the Political Club, and he assisted Lord Overstone in the publication of his lordship's miscellaneous tracts on political economy. In social life he was hospitable, genial, and warm-hearted, and was

esteemed by a large circle of friends who will deeply lament his loss.

Notes.

PRINCE CONSORT MEMORIAL.—The artists entrusted with the execution of the sculpture of the Prince Consort Memorial in Hyde Park, are the following:—Messrs. Foley, Macdowell, Marshall, Weekes, Bell, Theed, Thornycroft, Lawlor, and Baron Marochetti. The four principal, or lower groups, for the four outer corners of the base of the structure, and representing the four quarters of the globe, are—Europe, by Mr. Macdowell; Asia, by Mr. Foley; Africa, by Mr. Theed; and America, by Mr. Bell. The four upper, or secondary groups, are—Agriculture, by Mr. Marshall; Manufactures, by Mr. Weekes; Commerce, by Mr. Thornycroft; and Mechanics, by Mr. Lawlor. The statue of the Prince is to be executed by Baron Marochetti, and the relieves by Mr. Philip and Mr. Armstead.—*Athenæum*.

ROYAL SOCIETY.—The Copley, Royal, and Rumford medals have this year been awarded as follows:—Copley Medal: Mr. Charles Darwin, F.R.S., for his important researches in geology, zoology, and botanical physiology. Royal Medals: Mr. Jacob Lockhart Clarke, F.R.S., for his researches on the intimate structure of the spinal cord and brain, and on the development of the spinal cord; Mr. Warren De La Rue, F.R.S., for his observations on the total eclipse of the sun in 1860, and for his improvements in astronomical photography. Rumford Medal: Dr. John Tyndall, F.R.S., for his researches on the absorption and radiation of heat by gases and vapours. It is especially satisfactory to find the work of a philosopher, who, like Darwin, is not only the author of numerous monographs of the most varied as well as the most valuable description, but has revolutionised biology by the introduction of new fundamental conceptions, so early and so fully recognised by the Council of the Royal Society.

ABYSSINIA.—M. Lejean, Vice Consul of France at Massana, has just returned home, having recovered his liberty from the prisons of the Emperor of Abyssinia in September last. It took him five weeks to travel from Gondar to Massana. M. Lejean gives a sad account of the French expedition under M. Bisson, which has been a total failure, and of which the members are in a state of the utmost misery, and thinking of nothing but how they shall find their way home. On his way home, M. Lejean visited a corner of the Nubian Soudan, governed by a Circassian, Monça Pacha, and afterwards went to Halaf by a new route to the country of Zenadéglé, where he was able to rectify several errors which had crept into the last charts by Petermann. M. Lejean brings back with him some documents said to be of great archaeological interest, concerning Adulis and other points of the Sampar coast. He is said also to have discovered several necropoli, and to have found seven Axoumite medals, which are so rare that there are said only to be five in all the European collections known. They bear the head of the sovereign on one side, and the Cross of Abyssinia on the other. He promises to publish shortly a map of the country of the Bogos, and some ethnographical information. M. Lejean is of opinion that a Greek colony was once established at Adulis and its neighbourhood.

Correspondence.

REVISED CODE.—**SIR,**—The task of criticising the public acts of a department of the State is one of difficulty and delicacy; and the more so, that we have every reason to believe that the one we criticise is one originating in a kindly desire to promote the great object we in common have at heart, and recommended by those who have given their most earnest attention to the subject.

To such, let us hope, however, that a line of fair and candid reasoning will be acceptable, and that anything that we may say will be fairly weighed and favourably considered. There is, it would appear to me, at the bottom of the whole subject involved in the Government payments in aid of schools, a question of the greatest importance, viz.:—Is it, or is it not, the duty of the State, either directly or indirectly, as a separate question to be afterwards determined, to educate, or provide for the education of its children. The State interferes in much smaller questions than this. It will not let me burn my hay-rick, if I thereby risk the hay-rick of my neighbour. It compels me to pay towards the support of the criminal and the suppression of crime. It compels me to provide medical attendance, and sick and old age allowance, for the pauper, although he may have spent and wasted his property and thrown himself upon my industry. Is not the duty of educating as strong as either of these? Is not prevention, if we look at it in this light only, better than cure? Is the soul or the body the subordinate part of us? If it be the duty of the State to educate, or, at least, to provide education, as I think must be admitted, let us then claim to be exempt from the unjust and unworthy charge that we are grasping at the aid of the State, that we are seeking to rob its coffers, when we, as volunteers whose services it accepts, are doing its work, and when the obligation clearly rests, not with that party which, in a spirit of true love, throws itself into the work, but with that which is benefited by the work and whose duty is all but gratuitously done for it by zealous and willing hands. In approaching, then, the question of the Revised Code, we should bear this position in mind, and look at it in the abstract, not whether the State should provide or supplement education, but whether the plan proposed by the Revised Code is the best for the performance of its duty. It is a very large question. We are living under a constitutional government which, in the eye of the law, recognises no class, but provides for and desires that the talent, of whatever class, however humble, should rise to the surface for the service of the State, and that every facility should be given to it. Again, in the eye of the same just laws, all are equal, and, whether born in a village or a town, we have a right to the same advantages, to the same development of talent. All contribute to the taxes. All have a right to the same advantages. The thoughtful and intelligent observer of our constitution will not question this; the justifier of class legislation or class education only will treat it as theory. We are not born to that class of life in which it has pleased God to place us, or many would be still peasants who are most justly among the highest and most distinguished of the land. Education, aiding their own talent, has raised them. Let us not then repudiate the means which has exalted and distinguished our nation, or kick down the ladder by which the wisest and greatest have risen to eminence. Such is my preface to the question of the Revised Code as an instrument, for as such only can I deal with it, and in doing this I am obliged to contrast it with its predecessor. Both were experiments, tentative experiments, as regards the promotion of education, but not, I am disposed to think, as regards the officers employed. We are trying new kinds of artillery and new armour for ships, but this would hardly justify the withdrawal of the pay of our officers or their dismissal; and I confess that I think that this applies, and with a stringent force, to those whom we have encouraged to devote themselves to a new profession, and promised a fixed and settled payment so long as they continued in that profession. But I pass this by for those to adjust whose duty it is to do so, and on whom the responsibility of carrying out the engagements of the country lies. I refer to it only because I look upon the salary of the certificated master or mistress as an apt and satisfactory means of adjusting the claim to which I have already alluded, viz., that of all classes of the country, whether rural or urban, to the same advantages, and to the same chance of rising to the surface and into

eminence by the cultivation of the talents with which God has endowed them. A poor country parish had a chance, by the choice of a high class of teacher, whose Government payment on his certificate came in aid of the poverty of the place, of securing the teaching which the local resources could not secure. In taking away this resource, or throwing it on the managers—which is the same thing—and reducing all possible payments to a question of head money, the Revised Code comes in aid only of those who ought least to want it, and starves those poor small places which are struggling under a difficulty in which the State denies them any sympathy. While talking, but a short time since, on the working of the Code, and expressing my regret at the reduction of almost one-half of the receipts in rural parishes, I was told that it worked admirably in London, and in the parish in which I then was, in which they had largely increased their receipts. But that parish includes some of the largest and handsomest squares in London, and we may safely put them as 50 houses in each square, in each of which no one could pretend to live under an income of £4,000 or £5,000 a year. Here it works well, and the receipts are largely increased. I will not enter on the question of population as a basis, but simply express my conviction that it is a most fallacious one, and that there is no large population where larger aid cannot be had by a zealous clergyman than in a poor but moderate-sized village. I am quoting the figures of the Archbishop of York, in his admirable address on the subject, when I say that “small parishes take little advantage of the Government regulations” and that while of large parishes only 8½ per cent. are without Government aid, of the smaller parishes, under 500 population, 91 per cent. are without this aid, and that while 8,851 parishes are reached, 11,024 are untouched and unaided. The comparatively few populous parishes are aided, which I have endeavoured to show least require aid, while the smaller and poorer and most numerous parishes, to which the requirements act necessarily as a bar, are left to their own resources. Let me pass on, that I may not occupy too much time, to the question of the standard requirements of the Revised Code. Perhaps, under the old code, elementary mechanical instruction was not sufficiently insisted on. I say perhaps, and speak with some reserve, because it is almost necessary, before we determine this, that we should determine what we mean by education. I must not enter into this, nor take up any defined line of argument, but simply assume that it means the discipline and instruction of the mind through the agency of its perceptions and faculties. I will not for a moment trust myself to believe that there can be understood by any one such an education as will enable an infant of six or a boy of ten years to do his duty in that class of life in which it shall have pleased God to place him. If a labourer, a labourer; if a mechanic, a mechanic; perpetuating, or trying to perpetuate, the very worst evils under which any country can labour, the evils of caste, or class, and degradation. Assuming education to mean discipline and instruction of the mind, there is a mean, it would appear to me, between disregarding the mechanics of education, if I may use the expression, as applied to R. W. A., as was the case when it was said by some that they cared not whether the boy could write or spell well if he could give intelligent answers, and that system which insists primarily and almost wholly on this elementary work, to the exclusion or disregard of the awakening of intelligence. The practical educator knows the variety of taste and character he has to deal with, and that he has not really struck the first note until he has found, in some special taste or inclination, the key-note on which the whole course of education depends. To one child some particular work is specially irksome; to a second, another; while each has a particular taste or inclination which may be profitably cultivated. Now, doubtless, discipline requires that these should be wisely and judiciously dealt with, but the division of labour

also requires a principle to which this country owes so much that they should have fair play. The greatest mathematicians, the greatest classics, the greatest lawyers and statesmen, have not always been the best writers. The men of science or inventive skill have not always been the best arithmeticians. The greatest divines and the most eloquent statesmen have not always been good readers. Indeed, in higher life, all these branches of education on which we almost exclusively insist, are grievously neglected. What, then, is the object of this low standard to which, after so short a trial of the old code, we have reverted? Is it not to lower the standard of education, and, as it were, convulsively to struggle out of a difficulty which we have ourselves created, without considering the effect it must necessarily have upon those anxious to raise the standard of education, and upon those struggling with the difficulties of poverty and the narrow-minded views of certain classes amongst our agricultural population? It may be said, therefore, and I think fairly, that the Revised Code has had an injurious effect upon the cause of education. The old code may have been imperfect; indeed, it was so; and in its provisions precocious and inconsiderate, but still it had a greater effect than that which has succeeded it, in raising the education of the country; and everything teaches us, from the great and Divine Exemplar of our holy faith to the humblest legislator, that if we wish to raise our poor fallen humanity, we must take a high standard, and set it in all its fulness before the world. On another ground, I think that we have fair reason to complain of the Revised Code, viz., that it does not carry out its own principle—the payment by results. If this principle were fairly and fully carried out, it might be the means of helping the poorest schools, where active and intelligent masters and managers cordially co-operating with them, produced the results contemplated by the Code; but a bar is put to this by the Council's requirements, and by that ingenious sophistry which has transferred the engagements and liabilities of the Government to the shoulders of the managers, under the pretence of its being necessary to protect those very claims and rights of the masters which they have created and now disregard. The Archbishop of York, in his address, to which I have already alluded, speaks of there being no reduction in the number of pupil teachers. It may be so, and I cannot dispute the correctness of his Grace's information, but there has hardly been time for this to show itself, and I cannot help fearing that it will show itself not only in the number, but in the inferiority of the class, whenever time has been allowed to develop the consequences of the change. Everything is in the downward scale. The money saved—the teaching lowered with the class and tone and standing of the teachers—and we cannot wonder if the vision of a well-taught, well-instructed people, adapted to an age of machinery and science, pales before the argument of £ s. d., which fulfils, but too often, the adage of being “penny wise and pound foolish.” We may squander in the punishment of crime what we might most righteously economise in its prevention, and pay highly for much degradation and depravity, which criminal statistics, unquestionable and uncontrovertible, show that we might have saved, by a sound education—not by reading, writing, and arithmetic, the miserable skeleton—the dry bones of education—but by the enlargement of the faculties—the cultivation of taste and the creation of that thirst for knowledge as a resource, which is what the Christian educator will strive to attain.—I am, &c., S. B.

STUDY OF GEOMETRY.—SIR,—In reference to Mr. J. Culverhouse's letter contained in the *Society's Journal*, 624, Nov. 4th, 1864, wherein he asks “why Euclid is still retained as a school book on the subject of the science of geometry?” which he considers “is rendered unnecessarily abstruse,” and “ill adapted to our youth,” and in which remarks I concur, I have only now to observe that a book exists containing all of the most useful theorems (not

"theories") and problems of Euclid, which are rendered so exceedingly simple in the demonstrations thereof, as to almost reach the point aimed at by your correspondent, viz., "the results given simply as observations and rules." The book I allude to is Dr. Hutton's "Course of Mathematics," the 1st vol. of which contains the desiderata in question.—I am, &c., T. S. BURT.

18, Wilton-place, N.W., Nov. 7th, 1864.

MEETINGS FOR THE ENSUING WEEK.

- MON. ...** R. Asiatic, 3.
R. Inst. of British Architects, 8.
Medical, 8½. Mr. A. Balmanno Squire, M.B., "On Diseases of the Skin caused by the Acarus." 2. Mr. Henry Lee, "On different Modes in which Constitutional Syphilis may be communicated."
TUES. ... Anthropological, 8.
Ethnological, 8. 1. Captain Burton, "On the Ethnology of Dahome." 2. Mr. T. B. Pridéaux, "On the Principles of Ethnology."
Civil Engineers, 8. 1. Discussion "On the Decay of Materials in Tropical Climates." 2. Mr. E. H. Clark, "Description of the Great Grimsby Docks, &c."
WED. ... Society of Arts, 8. Dr. William Fairbairn, "On the Application of Iron to the Purposes of War and Naval Construction."
Archæological Assoc., 8½. 1. Dr. Brushfield, "On Roman Intaglios found at Petriana, on the Great Wall of Hadrian." 2. Mr. Pettigrew, "On Sepulchral Crosses at Ilkley and in the neighbourhood of Leeds." 3. Mr. Syer Cuming, "On Forged Antiquities in Bronze."
Geological, 8. 1. Sir W. E. Logan, "On the Occurrence of Organic Remains in the Laurentian Rocks of Canada." 2. Dr. J. W. Dawson, "On the Structure of certain Organic Remains from the Laurentian Limestones of Canada." 3. Mr. T. Sterry Hunt, "On the Mineralogy of certain Organic Remains from the Laurentian Limestones of Canada." Communicated by Sir W. E. Logan. 4. Mr. W. Keene, "On the Coal-measures of New South Wales, with Spirifers, *Glossopteria*, and *Lepidodendron*." Communicated by the Assistant-Secretary.

Patents.

From Commissioners of Patents Journal, November 11th.
GRANTS OF PROVISIONAL PROTECTION.

- Ammonia, manufacture of—2526—R. A. Brooman.
Anchors, construction of—2604—F. Martin.
Artillery, projectiles for—2622—W. Pitts.
Battens—2630—J. Smith.
Blast furnaces—2639—R. A. Brooman.
Boot and shoe making, manufacture of—2563—J. Brownhill.
Brewing and distilling, apparatus employed therein—3598—W. L. Tizard.
Buttons, &c.—2610—G. Davies.
Capes, &c.—2624—J. Emary.
Carriages, &c., reducing the friction of moving parts of—2562—M. Henry.
Chain cables, working of capstans, &c.—2600—W. H. Harfield.
China, articles of—2524—L. Clauss.
Clay, moulding the same into bricks and tiles—2636—J. Heap and T. Jolley.
Cotton pods, breaking the husks of—2554—E. Tomlinson and J. Jones.
Cotton, spinning and doubling—2508—W. B. Haigh and S. Barlow.
Envelopes—2558—A. D. Dhe.
Fabrics, woven—2496—J. Collinge.
Fire-arms and cartridges—2602—G. Davis.
Gas and atmospheric air, carburation of—2560—J. Cassell.
Houses, chimneys and flues for—2542—W. H. Kelsey.
Indigo, method of obtaining from textile materials—2156—J. F. P. Hugouenep.
Iron, manufacture of—2581—W. Taylor, H. Harrison, and G. Brown.
Jute—2654—R. Hart and J. F. Calder.
Lace, dressing—2345—W. Carter.
Ladies' skirts—2579—J. C. A. Henderson.
Lamps, wind and chimney holders for—1670—B. Whitehouse and C. Priestland.
Looms for weaving—2640—S. Shaw.
Matches, &c., receptacles for—2620—G. Betjemann, G. W. Betjemann, and J. Betjemann.
Metals, cleaning and polishing the surfaces of—2354—G. P. Wheeler and J. F. Gloyd.
Metals, pressure to the rolling and drawing of—2620—M. A. F. Menzies.
Moulding and planing wood, machinery for—2608—H. Wilson.
Piles, driving and drawing—2528—J. Robbins.
Postal and other purposes, stamping applicable to—2606—C. H. Gardner and C. Engllah.
Powder magazines for storing, &c.—2628—R. Hookham.

- Projectiles—2015—J. H. Huxley.
Propellers—2626—E. E. Colley.
Pumps—2548—W. E. Newton.
Railways, signalling on—2638—J. Tate.
Railway trains, signalling on—2616—J. Scarisbrick.
Rotary engines—2596—W. E. Newton.
Screw jacks, &c.—2625—A. Muir.
Screw presses, &c.—2617—A. Muir.
Sea wrack grass, treatment of—2522—E. Moride.
Signals or alarums—2558—T. Corbett.
Silcer, bean—2530—J. Batkin.
Smelling bottles—2658—Charles May.
Steam boiler, consuming smoke in—2632—R. A. Brooman.
Steam-bollers—2550—F. Wise.
Stoves, construction of—2534—A. Hippinus.
Sulphuric acids, concentrating and distilling—2634—W. Clark.
Textile fabrics, composition for waterproofing, &c.—2656—P. A. Le Comte de Fontaine-moreau.
Titanic iron sands—2650—B. F. Brunel.
Tubes, securing in tube sheets—2170—E. R. Lloyd and S. Lloyd.
Wax, preparation of artificial—2562—W. Clark.
Weaving ornamental fabrics—2662—J. Cunningham and R. Cunningham.
Woven fabrics, manufacture of—2592—W. H. Ablett and J. B. Balne.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

- Corks, &c.—2716—W. Davies, G. Cate, and W. Cate.
Rivets, fastening of—2746—G. Haseltine.

Registered Designs.

- Ladies' Safety Pocket—Sept. 30—4661—Alfred Chas. Hawes, 35, Dame-street, Packington-street, Ilkington.
A Purse—Oct. 5—4662—C. G. Arnold and Co., Leipzig, Germany.
Utilitarian Boot and Shoe Stud Rivet—Oct. 15—4664—John Cadwallader, Madeley, Shropshire.
Chadburn's Lanterns for producing enlarged images upon a screen, &c., similar to the magic lantern, from opaque bodies, engravings, drawings, photographs, reliefs, natural objects, and for dissolving the same images one into another—Oct. 19—4665—Charles Henry Chadburn, Liverpool.
Latch for doors, cupboards, and other articles—Oct. 21—4666—William Tonks and Sons, Birmingham.
Grass Cutting Machine—Oct. 22—4667—William Smith, Barnard Castle, Durham.
A Glove Fastener—Oct. 24—4668—J. W. Williams, Worcester.
A Set of Fastenings for the Stay Buak—Oct. 24—4669—Drew and Son, Bath.
The Fragrant Cloud Maker, or "La Bouffée Odorante et Frigorifique"—Nov. 11—4670—Messrs. Piesse and Lubin.
A Double Laundry Trough—Nov. 14—4671—Thos. Bradford, Fleet-street.
A Tobacco Pipe—Nov. 14—4672—James McAlpin, 28, Victoria-street, Manchester.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

Nov. 30.—“On the Mechanical Conditions of Railway Working to Prevent Destructive Wear and Risk.” By W. BRIDGES ADAMS, Esq.

Dec. 7.—“On the Construction, Retardation, Safety, and Police of Railway Trains.” By W. BRIDGES ADAMS, Esq.

Dec. 14.—“On Irish Industries; and the Irish International Exhibition of 1865.” By Sir ROBT. KANE.

CANTOR LECTURES.

There will be three Courses of “Cantor” Lectures on the following subjects during the ensuing Session:—

“On the Reproduction of Natural Forms by Art and Manufacture.” By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

“On the Application of Geology to the Arts and Manufactures.” By Professor D. T. ANSTED, M.A., F.R.S.

“On the Application of Chemistry to the Arts.” By Dr. F. CRAIG CALVERT, F.R.S.

The following is a syllabus of Mr. Hawkins's course, with the dates of delivery:—

Dec. 12th.—LECTURE I.—INTRODUCTORY:—On the nature and probable influence of museums of natural history and art collections, and their effect on the public mind and taste. (Illustrated.)

Dec. 19.—LECTURE II.—Demonstrations of the unity of plan in the external forms of animals, the just appreciation of which facilitates the work of the artistic producer, and adds to the enjoyment of the intelligent possessor of works of art.

Jan. 16th, 1865.—LECTURE III.—On the varieties of artistic treatment of the forms of animal and vegetable life—pictorial representation; conventional ornamental, allegorical, and symbolic combinations of animal forms.

Jan. 23rd.—LECTURE IV.—On the fitness of designs, and their adaptation to the conditions of the materials in

which they are to be produced. (Demonstrated by metal-work processes, sand-moulding, casting, and chasing).

JAN. 30th.—LECTURE V.—On Ceramic Manufactures, with the Influence of the material on the design and its successful production—modern Terra Cotta, Della Robbia ware, Majolica, and Parian.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture.

Proceedings of the Society.

SECOND ORDINARY MEETING.

Wednesday, November 23rd, 1864; The Duke of Somerset, K.G., First Lord of the Admiralty, in the chair.

The following candidates were proposed for election as members of the Society:—

Barker, Charles Stuart, 12, Buckingham-street, Adelphi, W.C.

Durham, Makin, Thorne Hall, Thorne, Yorkshire.

Gale, William Joseph, 32, Torrington-square, W.C.

Hale, William, 6, John-street, Adelphi, W.C.

Kirchner, John, Peckham-common, S.

Partridge, William, 48, Newgate-street, E.C.

Pistrucci, Valerio, 28, Camden-street, N.W.

Pito, Frederick Robert, 38, Bloomsbury-square, W.C.

Pitman, E., 2, Ledbury-road, W.

Pittar, Arthur, 4, Kensington Park-gardens, W.

Rowlands, Percy Jones, 24, Notting-hill-terrace, W.; and

India Office, Westminster, S.W.

Slater, Robert, 104, Fore-street, E.C.

Smith, William Binns, 7, New-square, W.C.

Thompson, F., South Parade, Wakefield.

Tichborne, Sir Alfred, Bart., Tichborne-park, Hants, and

13, James's-street, Buckingham-gate, S.W.

Todd, William, 24, Wellington-road, St. John's-wood,

N.W.

Tozer, Thomas, 55, Dean-street, Soho, W.

Van de Weyer, M. Sylvain (Belgian Minister), 3, Grosvenor-square, W.

Venning, Walter C., 9, Tokenhouse-yard, E.C.

Verschoyle, Colonel H., 23, Chapel-street, Belgrave-square, S.W.

Wilson, George, Cyclops Steel and Iron Works, Sheffield.
Wingate, James Forman, Club-chambers, 15, Regent-street, S.W.

The Paper read was—

ON THE APPLICATION OF IRON TO THE PURPOSES OF NAVAL CONSTRUCTION.

By WM. FAIRBAIRN, Esq., LL.D., F.R.S.

From the earliest period of history to the present high state of civilisation, we behold a long and interesting succession of improvements in the construction of weapons of war. Man in his savage state contrived instruments of aggression as well as defence. Tomahawks, spears, and arrows composed of wood, shod with stone or bone, were adopted. As he advanced in civilisation, and became acquainted with minerals, he had recourse to a rude description of manufacture by reducing the ores and extending their uses to the purposes of peace as well as to the art of war. In fact, he found that the application of heat to the iron ores produced a semifluid or ductile mass, that could be drawn or consolidated, under a series of blows, into the required forms calculated to supply his wants. It was in this way that the early workers in iron—the Tubal Cains of former days—produced weapons for attack and defence. No doubt they would soon find—once the discovery was made—that iron, at different degrees of temperature, and under different conditions of time and the heat to which it was exposed, would assume the different forms of rigidity, ductility, &c.; and, without any knowledge of combined carbon, oxygen, &c., as known in modern times, they actually found, at a later period, that a certain process, under these conditions, produced steel, from whence the famous weapons known as the “Blades of Damascus” were made.

From these early stages of manufacture to the middle of the last century, we have little to boast of in the production of iron and steel. Something was certainly done during this long interval, but we have no traces of any important improvement until 1784, when Cort first introduced his invention of the puddling furnace and the rolling of plates and bar iron. Hammered iron plates were occasionally made, but seldom used unless for special purposes; and it was not until the introduction of rolls that anything in the shape of rolled plates could be obtained. At that time, and for several years subsequently, little or nothing was done to encourage the manufacture, but the new process of rolling simplified the operation and gave greatly increased facilities for the manufacture of this important article of commerce. Rolled plates were first employed in the construction of boilers; and those of the haystack form were made as early as 1786, and were chiefly employed for raising steam for the atmospheric pumping engines of Cornwall, and those for the collieries of Northumberland and Durham. More recently, or about the same date, Mr. Watt introduced the waggon-shaped boiler for his reciprocating sun and planet-wheel engine, but we have no traces of iron boats or ships at a date antecedent to that of Cort and Watt.

At the commencement of the present century it is more than probable that the first construction of iron canal boats took place; and we have evidence of their existence in Staffordshire about the year 1812 or 1813. From that time to the present iron boats have been successfully employed on canals.

From 1812 to 1822, to use a more familiar expression, there was an interregnum of progress for a period of ten years, and we hear nothing of iron as a material for ship-building, till the Horsely Company built the *Aaron Manby*, which was sent to London in sections, reconstructed in one of the docks, and navigated to Havre and Paris by the late Admiral Napier.

It was supposed that the success of the *Aaron Manby* would have stimulated exertions in the same direction, but important discoveries, like other things of great magnitude, require time to bring them to maturity, and another period of rest ensued, from 1822 to 1829, when a new discovery was made by Mr. Houston, of Johnstone, near Paisley, in which it was found that a light boat, with two horses, had sufficient power to convey passengers on a canal at the rate of nine to ten miles an hour. This discovery was made at a time when a new and important era in the history of transit on railways burst unexpectedly upon the public in the experimental tests and competitive trials of locomotive engines at Rainhill. The results of these trials created alarm in the minds of all the canal proprietors of the kingdom. They became anxious about their property; and the speed of ten miles an hour, as attained by Mr. Houston in his gig-boat, was the only gleam of hope left to enable them to meet, with anything like success, the alarming and powerful competition of the rail and locomotive.

Things were in this state when the governor and council of the Forth and Clyde Canal employed the writer to institute a series of experiments to determine the law of traction, and account for the phenomena of the absence of surge at high velocities on canals. These experiments were conclusive and interesting, and the report was published shortly afterwards, at the request of the governor and council of the Forth and Clyde Canal Company. In this report will be found a detailed account of the experiments and the conclusions and recommendations arrived at, the most prominent of which were the introduction of iron vessels and steam on the locomotive principle as a substitute for horses. Acting upon this recommendation four steam vessels were constructed at Manchester, one a twin-boat, with the paddle-wheel in the centre, and a second, the *Lord Dundas*, with the paddles recessed into the dead wood of the stern. The first was an experimental boat, but the second plied for several years as a passage boat between Port Dundas and Lock 16.

Simultaneous with these vessels another and a larger iron vessel, 84 feet long and 14 feet beam, with recessed paddles in the stern, was also built at Manchester in 1831, and navigated through the locks of the Mersey and Irwell to Liverpool, and from thence to Greenock. This was the second iron vessel that put to sea, if we except the *Lord Dundas* light boat, which performed the same voyage from Liverpool to Glasgow in the previous year. The name of this vessel was the *Manchester*, and for many years it was employed as a coasting vessel, carrying goods and passengers between Port Dundas, Grangemouth, and Dundee.

During the time of these constructions Messrs. John and MacGregor Laird were engaged in similar undertakings for the Irish canals, and were present at most of the experimental trials of light boats on the Irwell. These boats were built at Birkenhead, and forwarded in sections to Ireland. About the same time, or shortly after the Manchester canal boats were introduced on the Forth and Clyde Canal, Messrs. Laird built the *Aburka*, a small iron vessel, that went out to Africa with the Landers and Mr. MacGregor Laird, for the exploration of the Niger. The whole of these vessels were confirmatory of the great superiority of iron over wood as a material for ship-building; and we have only to refer to the extensive use and enormous increase that have taken place in its application, not only in this country, but in every maritime state of the globe, to be convinced of the soundness of the principles and the great superiority of the iron ship.

Having briefly noticed the origin and subsequent improvements that have taken place in iron ship-building, it is important that the naval architect should have all the information that can be obtained, and for this purpose we have on this very important question to direct attention to the following divisions of the subject:—

1st. The strength of plates when torn asunder by a direct tensile strain in the direction of the fibre, and when torn asunder across it.

2nd. On the strength of the joints of plates when united by rivets as compared with the plates themselves.

3rd. On the resistance of plates in varied forms of construction to the force of compression.

And lastly. On the distribution, strength, and value of wrought-iron plates and frames as applied to ships and other vessels.

On the first of these, where the iron plates were torn asunder in the direction of the fibre and across it, the following results were obtained:—

TABLE I.

DESCRIPTION OF PLATES.	Mean breaking weight in the direction of the fibre in tons per square inch.	Mean breaking weight across the fibre in tons per square inch.
Yorkshire Plates	25-770	27-490
Yorkshire Plates	22-760	26-087
Derbyshire Plates	21-680	18-650
Shropshire Plates	22-826	22-000
Staffordshire Plates	19-563	21-010
Mean.....	22-519	23-087

From the above it will be observed that the average strength of plates is about 22½ tons to the square inch, the maximum being in favour of the Yorkshire plates, and the minimum those of Staffordshire.

It would probably be unfair to class plates with bar iron of the same quality, as bar iron is much more elongated and drawn into fibre in passing through the rolls than the same material when drawn into plates; we may, however, compare plates with bars experimented upon by the late Mr. Telford, who found, in his experiments to determine the strength of different irons previous to his construction of the Menai Suspension Bridge, that out of nine fagoted specimens, selected from the Swedish, Welsh, and Staffordshire irons, he obtained a tenacity of 29-25 tons per square inch.

	Tons.
Captain Brown's experiments for the same purpose gave.....	25-00 per sq. inch.
Minord and Desames'	25-00 "
Yorkshire plate experiments ...	24-50 "
Shropshire plates	22-82 "
Derbyshire plates	21-68 "
Staffordshire plates	20-32 "

Giving a mean tenacity for plates of 23-22 tons per sq. in.

Comparing this with the strength of bar iron from the best material, and making allowance for the latter having been worked, rolled, and drawn into fibre to a greater extent than plates, the difference in strength is not so great as might have been expected, being in the ratio of 29 : 23 or 1 : .8 nearly.

Plates of ordinary manufacture, or such as are used in ship-building, seldom exceed 20 tons to the square inch. Unfortunately, many of these are considerably under that mark, but on no account should any plate be allowed to enter into the construction of a sea-going vessel under a tensile strain of from 20 to 22 tons per square inch. Small vessels, such as boats for canals and rivers, may venture upon an inferior standard of quality, but even with this allowance there is no economy in the use of bad material, which is neither safe nor durable.

DUCTILITY, ELONGATION, &c.—We have already noticed that ductility is a property highly valuable in iron, and, we may add, when combined with tenacity it becomes more so; in fact, ductility is the true measure of strength and of its practical utility. These properties being of great importance in the manufacture of iron, it may

be useful to give a few examples, derived from recent experiments, illustrating the principle on which it is supposed that good iron yields and becomes attenuated when acted upon by forces which draw it in the direction of the fibre.

It has been stated that iron, like most other metals, is of a ductile character. In this respect, however, it is inferior to gold, silver, and platinum, but it is in advance of copper, zinc, and tin, and may be considered superior to any of these metals on account of its tenacity, and from this we derive its adaptation to the art of construction and its value as an article of commerce. Iron is, therefore, of inestimable value, and, combining properties such as those enumerated, it becomes one of the most important and useful of metals.

The following experimental results were derived from seven different thicknesses of iron plate. They were obtained from four different firms, and marked A, B, C, and D, as under:—

- A. Six specimens of iron plates.
- B. Seven specimens.
- C. Seven specimens, homogeneous metal.
- D. Seven specimens, rolled iron.

The whole of these specimens were torn asunder by a tensile strain, and recorded in the following summary:—

TABLE II.

Summary, giving mean Tensile Strength of each Series of Plates, or Static Breaking Strain.

Approximate thickness of the Plates in inches.	TENSILE BREAKING WEIGHT PER SQUARE INCH OF SECTION.				Mean of Plates of the same thickness in tons.
	A Plates.	B Plates.	C Plates.	D Plates.	
inch.	tons.	tons.	tons.	tons.	tons.
¼	24-344	24-167	30-783	17-470	24-171
½	26-750	23-220	33-684	11-065	23-430
¾	---	29-433	30-913	26-473	---
1½	24-158	22-289	26-197	25-158	24-453
2	25-348	23-657	27-038	24-634	25-169
2½	24-110	23-921	27-506	22-732	24-569
3	26-039	23-640	27-386	24-159	25-031
Mean of thin plates	25-047	25-006	31-770	18-333	---
Mean of thick plates	24-844	23-384	27-032	24-171	---
Mean of all of one make ...	24-792	24-319	29-063	21-669	..

The order of merit in the thinner plates is, (1) C; (2) B; (3) A; (4) D. With thicker plates it is—(1) C; (2) A; (3) D; (4) B. The mean of the whole gives (1) C; (2) A; (3) B; (4) D.

The homogeneous metal plates exhibit throughout the highest tenacity, but the tenacity decreases as the plates are made thicker. Of the iron plates, those marked A are most uniform in strength, the extreme difference being 1-64 tons. The B plates vary to the extent of 7-183 tons, and the D plates 14-103 tons, but the quarter and half-inch plates of the latter series would appear to have been burnt or injured in the manufacture.

Taking the means given in the last column, we see that in the average there is no great difference between the thicker and thinner plates. The extreme variation in these means is 1-74 tons. If we compare these means with the corresponding mean densities, there is an evident correspondence, thus—

	Density.	Tenacity.
1½ inch plates.....	7-7471	24-453
2-inch plates	7-7684	25-169
2½-inch plates.....	7-7660	24-569
3-inch plates	7-7666	25-031

Here the density and tenacity increase and diminish together. The same correspondence will be found, gene-

rally speaking, in each individual case on comparing the two tables, but there are exceptions in the case of the D plates. Taking into account the fact that the specimen employed in obtaining the specific gravity was cut at a distance of about 10 inches from the part broken by tension, the coincidence is sufficiently striking. The comparison holds good if we take the means of plates of the same manufacture, with one exception—

	Density.	Tenacity.
A plates	7.8088	24.644
B plates	7.7035	23.854
C plates	7.9042	27.082
D plates	7.6322	24.171

TABLE III.

Summary, giving the ultimate elongation per unit of length.

Approximate thickness of the plates in inches.	ULTIMATE ELONGATION PER UNIT OF LENGTH.				Mean of Plates of the same thickness in tons.
	A Plates.	B Plates.	C Plates.	D Plates.	
Inch.					
$\frac{1}{8}$.0620	.0300	.2550	.0080	0.0890

$\frac{3}{8}$..	.1000	.2000	.0400	0.1160
$\frac{1}{2}$.1763	.1462	.1925	.1925	0.1769
2	.3050	.2625	.3450	.1788	0.2703
2 $\frac{1}{2}$.2880	.3200	.2950	.1600	0.2658
3	.3200	.2650	.2575	.2333	0.2689
Mean of thinner plates0690	.0566	.1880	.0197	...
Mean of thicker plates2723	.2450	.2725	.1918	...
Mean of all the plates2046	.1650	.2303	.1176	...

In this table the order in which the different series of plates stand with reference to ultimate elongation nearly coincides with the order in which they stand in reference to tenacity if the means of plates of the same manufacture are compared; but, on the other hand, if we compare the means of plates of the same thickness, we find that on the whole the ultimate elongation increases as the plates become thicker, whilst no law of this kind could be perceived in the mean tenacities.

Mr. Mallet has introduced a new co-efficient of strength of considerable importance in these inquiries, namely, the dynamic resistance to rupture, or foot pounds of work done in rupturing the material. This may be estimated with sufficient accuracy by multiplying the breaking weight in lbs. by half the ultimate elongation, and from thence we derive the following results:—

TABLE IV.

Mr. Mallet's Co-efficient of work done in causing rupture, corresponding with resistance to impact.

Approximate thickness of the plates in inches.	FOOT POUNDS OF WORK CAUSING RUPTURE.				Mean of Plates of the same thickness.
	A Plates.	B Plates.	C Plates.	D Plates.	
Inch.					
$\frac{1}{8}$	1690.5	812.0	3802.7	156.5	2665.4
$\frac{1}{4}$	2191.8	1040.2	3773.7	137.4	1785.8
$\frac{3}{8}$...	3296.5	7201.5	1164.0	3806.0
$\frac{1}{2}$	4767.5	3681.3	5648.0	5424.0	4872.7
2	8659.0	6690.2	10448.0	4933.1	7682.6
2 $\frac{1}{2}$	7776.8	8873.4	9087.2	4078.7	7371.7
3	8973.7	6987.0	7678.0	6312.7	7767.9
Mean of thinner plates ...	1941.1	1716.2	6592.6	493.3	...
Mean of thicker plates	7544.2	6475.5	8206.3	5186.9	...
Mean of plates of same make	8676.0	4436.8	8006.5	3174.8	...

It will be noticed that the numbers given in the case of the thinner plates are very variable, in consequence of the great fluctuations in the value of the ultimate elongation in those plates. This irregularity would have been eliminated if several specimens of each had been tried, or, still better, if the specimens had been so long that the elongation of a much greater extent of metal could have been ascertained. The results obtained in the thicker plates, with precisely similar round bars, are more uniform.

Bearing this in mind, the table exhibits several remarkable results. First, taking the means of plates of the same thickness, it appears that the dynamic resistance increases progressively as the plates increase in thickness; in fact, the thick plates exhibit 2 $\frac{1}{2}$ times the resistance of the thinner ones. The only exception to this general law is the quarter-inch homogeneous metal plate, which was extremely ductile.

Then, in the next place, it is to be observed, that the dynamic resistance increases with the thickness of the plates in a higher ratio in the iron plates than in the homogeneous metal plates, thus:—

DESCRIPTION OF PLATES.	Thinner Plates. Foot Pounds.	Thicker Plates. Foot Pounds.	Ratio.
A Plates } Iron.	1941.1	7544.2	1 to 3.82
B Plates }	1716.2	6475.5	1 to 3.77
D Plates }	493.3	5185.9	1 to 10.52
C Plates Steel.	6592.6	8265.3	1 to 1.25

The result of this is that the superiority of the homogeneous metal to iron is very striking in the thin plates, but becomes less and less as the plates increase in thickness. Thus, taking the best of the iron plates, namely, series A, for comparison, we have the following ratios between the iron and steel:—

THICKNESS IN INCHES.	A. Plates Foot-pounds.	C. Plates Foot-pounds.	Ratio of Dynamic resistance.
$\frac{1}{8}$ -inch	1690.5	8202.7	1 to 5.21
$\frac{1}{4}$ -inch	2191.8	3773.7	1 to 1.72
$\frac{3}{8}$ -inch	7201.5	...
$\frac{1}{2}$ inches	4767.5	5648.0	1 to 1.19
2 inches	8659.0	10448.0	1 to 1.20
2 $\frac{1}{2}$ inches	7776.8	9087.2	1 to 1.17
3 inches	8973.7	7878.0	1 to 0.88

In this table we see that the ratio decreases progressively with great regularity from 1 : 5.21 to 1 : 0.88; that is, the work done in rupture is with $\frac{1}{8}$ -inch plates five times as great with homogeneous metal as with iron, but the superiority decreases, and with 3-inch plates the resistance of the iron is 12 per cent. greater than that of the homogeneous metal. This result precisely corresponds with the results obtained in the trials with ordnance.* Thus, if we take the mean between the thinnest plate which resisted the shot of any given weight, and the thickest which was penetrated by it, as the maximum thickness of penetration with that projectile, we have from the experiments at Shoeburyness the following results:—

RIFLED GUN. Projectile in lbs.	Weight of Projectile in lbs.	Least thickness which would resist the shot in inches.		Ratio of resistance of plates of equal thickness.
		A Plates.	C Plates.	
Wall piece	0.344	0.87	1.62	1 : 1.97
Armstrong	6.25	1.25	1.15	1 : 1.18
"	11.56	1.75	1.75	1 : 1.00
"	24.81	2.25	2.50	1 : 0.81

* See Mr. Fairbairn's Experimental Researches, 1st Report of the Special Committee on Iron.

The results in this table are only roughly approximate; but they show a decreasing resistance in the C plates when compared with the A plates. The results in the last column strikingly correspond with those in the preceding table, if plates of the same thickness be compared. On comparing table 4, giving Mallet's coefficient, with the specific gravities, similar correspondence is observable to that already noticed in the case of tensile breaking strain. The exceptions also occur in the same series, namely, the D plates. Of the iron plates of different manufacturers, the A series throughout manifest the greatest amount of dynamic resistance. Next to it the hammered plates of series B, and, lastly, the rolled plates of series D. Taking the thicker plates, which give the most accurate results, and employing the iron plates of series A as a standard of comparison, we have the following ratio of dynamic resistance:—

A Plates.....	1000
B Plates.....	858
C Plates.....	1095
D Plates.....	688

The maximum difference amounting to 41 per cent. between C and D, and 31 per cent. between A and D.

To the above extract from the Report of the Special Committee on Iron, we may add the results of some experiments on the tensile strength of S C ~~W~~ bars, conducted some years since at Woolwich, by Mr. Lloyd, Inspector of Machinery. To that gentleman we are indebted for the following results:—

TABLE V.
Summary of Results, Tensile Strength of Bars.

Length of Bar in inches.	Diameter of Bar in inches.	Breaking Weight in Tons.	Elongation in inches.	Elongation per unit of length.
120	1.375	32.210	26.0	.216
42	1.375	32.125	9.8	.233
36	1.375	32.350	8.8	.244
24	1.375	32.000	6.2	.258
10	1.375	32.290	4.2	.420

In another series of experiments it was found that the continued strain of three-fourths of the breaking weight had no effect upon the bars, and that it might have been prolonged indefinitely without injury to the cohesive force by which the particles were united. These facts, although exceedingly interesting at the time, have since been carefully investigated, and, having to refer to them in the sequel, it will be sufficient for our present purpose simply to advert to the plastic nature of the iron by which the bars sustained an amount of elongation exceeding that of most other irons.

It appears from Table V. that the rate of elongation of wrought iron bars increases with the decrease of their length; thus, while a bar of 120 inches has an elongation of .216 inch per unit of length, a bar of ten inches has an elongation of .420 inch per unit of its length, or nearly double what it is in the former case. The relation between the length of a bar and its maximum elongation per unit of length, may be approximately expressed by the following formula, viz.:—

$$l = .18 + \frac{2.5}{L}$$

where L represents the length of the bar, and l the elongation per unit of length of the bar. These results are of some value, as they exhibit the ductility of wrought iron at a low temperature, and also the greatly increased strength which it exhibits with a reduced section under strain.

2ND. ON THE STRENGTH OF THE JOINTS OF PLATES WHEN UNITED WITH RIVETS, AS COMPARED WITH THE STRENGTH OF THE PLATES THEMSELVES.—To ascertain

the facts and to show how nature works in this direction, we are compelled to have recourse to the old but certain test of experiment. This appeared to me as the only certain method of arriving at truth in physical research. Resorting, therefore, to this expedient it will be necessary to note, what appears obvious to the most casual observer acquainted with mechanical constructions, that to unite plates together so as to make the joints as secure as if they were continuous and homogeneous in character is a desideratum. It would be desirable, for example, to have the longitudinal sheathing of our ships in strips or plates without joints; but this could not be done by welding, and here we have to resort to the expedient of uniting them together by bolts or rivets. Now it has been found that the latter process is by far the strongest and most endurable, as the rivets are generally put in hot and are hammered, or, what is decidedly preferable, compressed by the riveting machine into the holes prepared for their reception. A good rivet requires a head on each side, the same as a bolt and nut, but there is this difference, that the rivet becomes, when carefully inserted, part and parcel of the plate, and, when duly proportioned as to size and number, is equal in strength to the plate itself, minus the part punched out by the rivets. It is therefore desirable in every case where plates have to be joined that they should be united by rivets.

In ship-building, and in every other construction where wrought-iron plates form the principal material, it is essential that this part of the inquiry should be explicitly and clearly understood. It is therefore most desirable that the question should be thoroughly investigated, and that all those engaged in constructions of this kind should be fully aware of their importance, not only as regards the acquisition of knowledge, but the heavy responsibilities which attach to works on which the lives and property of the nation and of individuals depend. Impressed with these views, I may venture to submit to the engineer and naval architect the results of experiments which from time to time, and for a long series of years, have engaged my attention. In attempting to unite plates by the insertion of rivets we have to consider:—

1st. PUNCHING.—Now this is a very important part of the shipbuilding process, first, that the holes should be clean and well cut, and that by a perfectly flat steel punch; secondly, the holes in the plates when put together, should be coincident, and have a common centre, and should cover each other. To accomplish this, it is desirable that the punching should be done, if possible, by a self-regulating machine, but when this cannot be accomplished, the greatest care should be observed on the part of the workman to see that the punching is executed so as to bring the holes to coincide, and not incur the anomalous condition of having them half blind—as it is technically called—or nearly blind altogether—a circumstance which in rough imperfect work too often occurs.

It is much to be regretted that more attention is not paid to these operations, as inaccurate punching is seriously detrimental to the plates; and there is nothing which causes more injury to the security and tightness of the joints than bad riveting. The remedy chiefly in use by workmen as a compensation for the want of coincidence, is to drive through both holes a tapered steel pin, or drift, forcing and tearing the plate in every direction; and in order that they should obey the dictates of physical force as administered by a sledge hammer, in the hands of one whose muscular developments are greatly in excess of the reflective functions of his brain, the holes are enlarged, and the rivet very imperfectly closed, at an oblique angle to the face of the plate. This is a process which cannot be too much condemned, and appears to be the strongest argument against the punch. Some engineers, to avoid this evil, insist on having the holes in the plates drilled, but, according to our judgment, this system is better adapted to bolts than rivets, as the

drill makes a perfectly parallel hole, which is never so sound nor yet so secure as that which comes from the punch; and for this reason, that in punching a hole through an iron plate, it is not exactly cylindrical, parallel, or smooth, but the frustum of a cone, and hence follows the superiority of the joint, as more closely incorporated with the plates. It will not be necessary in this place to determine the law by which this particular form is attained, suffice it to observe that the diameter of the punch is to the hole in the die as 1:1.15 or 1:1.20 for ordinary work, and we have therefore a hole in the plate or the piece punched out with oblique sides, the angles of which vary in the ratio of the thickness of the plates, and these with coincident holes form a sound and perfect rivet. Now this form of hole is not injurious but of great value as regards the strength of the joints, as the conical form of the holes is equivalent to a countersunk rivet on each side. It is moreover highly advantageous in ship-building, where the rivets are countersunk on one side, and where a perfectly smooth surface is required for the passage of the currents on the other.

To arrive at the strongest form of joint, it is necessary in this case to punch the plates so that the narrow sides of the holes are in contact. This is the more essential, as the heads of the rivets are easier formed, and the holes better filled, when performed either by the hammer or by compression. By the latter process—machine riveting—the joints are brought closer together by contraction as the rivet cools, and the adhesion of the two surfaces is greatly augmented.

RIVETING.—During the early stages of iron construction, and as recent as the time to which we have alluded when iron shipbuilding was first introduced, there was only one system of uniting the joints of iron plates, namely, the overlap single-riveted joint. Now it is widely different, as the variety of purposes to which plates are applied renders a new and entirely different principle of riveting essential. When the double-riveted joint came into use is uncertain, but its advantages were first shown during the progress of my earlier experiments. These experiments were conclusive as to the value of the double riveted joint, but a new system of iron construction has been developed in the experimental researches which led to the form and construction of the Britannia and the Conway tubular bridges. In these structures it was imperative that the joints submitted to tension should be equal, or at least approximate closely to the strength of the solid plate; and after a great number of experiments it was found that the old system of single and double joint riveting was not only inapplicable but weak and insecure. This insecurity led to a more extended series of experiments, a summary of results of which I have now to record for the benefit of those who are not acquainted with the facts, and to whom it may be useful in the varied forms of construction as applied to iron ships and bridges.

GENERAL SUMMARY OF RESULTS AS OBTAINED FROM EXPERIMENT.

No. of Experiments.	Cohesive strength of the plates. Breaking weight in lbs. per square inch.	Strength of double-riveted joints of equal section to the plates, taken through the line of rivets. Breaking weight in lbs. per square inch.	Strength of single-riveted joints of equal section to the plates, taken through the line of rivets. Breaking weight in lbs. per square inch.
1	57,724	52,352	45,743
2	61,579	48,821	36,606
3	58,322	58,286	43,141
4	50,983	54,594	43,515
5	51,180	53,879	40,249
6	49,281	53,879	44,715
7	43,805	...	37,161
8	47,062
Mean.	52,486	53,635	41,590

The relative strengths will therefore be—

For the plate.....	1,000
Double-riveted joint.....	1,021
Single riveted joint.....	791

From the above it will be seen that the single-riveted joints have lost one-fifth of the actual strength of the plates, whilst the double-riveted have retained their resisting powers unimpaired. These are important and convincing proofs of the superior value of the double joint; and in all cases where strength is required this description of joint should never be omitted. It appears when plates are riveted in this manner, that the strength of the joints is to the strength of the plates of equal sections of metal as the numbers,—

Plate.	Double-riveted joint.	Single-riveted joint.
1,000	: 1021	and 791
In a former analysis it was 1,000	: 933	and 731

Which gives us a mean of 1,000 : 977 and 761

which in practice we may safely assume as the correct value of each. Exclusive of this difference, we must however deduct 30 per cent. for the loss of metal punched out for the reception of the rivets; and the absolute strength of the plates will then be to that of the riveted joints as the numbers 100, 68, and 46. In some cases, where the rivets are wider apart, the loss sustained is however not so great; but in boilers and similar vessels, where the rivets require to be close to each other, the edges of the plates are weakened to that extent. In this estimate we must however take into consideration the circumstances under which the results were obtained, as only two or three rivets came within the reach of experiment; and, again, looking at the increase of strength which might be gained by having a greater number of rivets in combination, and the adhesion of the two surfaces in contact, which in the compressed rivets by machine is considerable, we may fairly assume the following relative strengths as the value of plates with their riveted joints:—

Taking the strength of the plate at100
The strength of the double riveted joint will be 70
And the strength of the single riveted 46

These proportions may therefore in practice be safely taken as the standard value of joints such as are used in vessels where they are required to be steam or water tight, and subjected to pressure varying from 10 to 100lbs. on the square inch.

RIVETS.—On this subject we have to consider the diameter, pitch, and length necessary to be observed in forming sound and tight joints without injury to the plates beyond the amount of metal punched out for the reception of the rivets. I have investigated this subject with great care, and, from my own personal knowledge and that of others, have collected a number of practical facts, such as long experience alone could furnish. From these data I have been enabled to compute the following table, which for practical use I have found highly valuable in proportioning the distances and strength of rivets in joints requiring to be steam or water-tight.

Table exhibiting the Strongest Forms and best proportions of Riveted Joints, as deduced from the Experiments and Actual Practice.

Thickness of plates in inches.	Diameter of rivets in inches.	Length of rivets in inches.	Distance of rivets from centre to centre in inches.	Quantity of lap in single joints in inches.	Quantity of lap in double joints in inches.
.19 = $\frac{3}{16}$.25	.68	1.25	1.25	For the double joint add $\frac{1}{4}$ to the depth of the single lap.
.25 = $\frac{1}{2}$.30	1.13	1.50	1.50	
.31 = $\frac{5}{16}$.35	1.38	1.63	1.63	
.38 = $\frac{3}{8}$.40	1.43	1.75	2.00	5-8
.46 = $\frac{7}{16}$.45	1.61	2.25	2.25	4-5
.53 = $\frac{1}{2}$.50	1.75	2.50	2.75	
.75 = $\frac{3}{4}$.75	3.25	3.00	3.25	

The figures 2, 1·5, 4·5, 6, 5, &c., in the preceding table are multipliers for the diameter, length, and distance of rivets, also for the quantity of lap allowed for the single and double joints. These multipliers may be considered as proportionals of the thicknesses of the plates to the diameter, length, distance of rivets, &c. For example, suppose we take three-eighths plates, and required the proportionate parts of the strongest form of joint, it will be—

$$\begin{aligned} \cdot 375 \times 2 &= \cdot 750 \text{ diameter of rivet, } \frac{3}{4} \text{ inch.} \\ \cdot 375 \times 4\frac{1}{2} &= 1\cdot 688 \text{ length of rivet, } 1\frac{1}{4} \text{ inches.} \\ \cdot 375 \times 5 &= 1\cdot 875 \text{ distance between rivets, } 1\frac{1}{4} \text{ inches.} \\ \cdot 375 \times 5\frac{1}{2} &= 2\cdot 063 \text{ quantity of lap, single riveted joint, 2 inches.} \\ \cdot 375 \times 5\frac{1}{2} + \frac{2}{3} &= 3\cdot 438 \text{ quantity of lap, double riveted joints, } 3\frac{1}{2} \text{ inches.} \end{aligned}$$

·75, 1·68, 1·87, 2·06, and 3·43 are therefore the proportionate quantities necessary to form the strongest steam or water-tight joints on plates three-eighths of an inch thick.

3rd. ON THE RESISTANCE OF PLATES, AS APPLIED IN DIFFERENT FORMS TO THE FORCE OF COMPRESSION.—We have already noticed, when treating of the tensile strain to which a ship is subjected, that another equally important force is in operation in the movements of the vessel—that of crushing or compression. This is more apparent in iron than in wooden structures, as thin plates are liable to distortion when forcibly compressed in the direction of their lengths; and in ship-building, as in tubular girder bridges, this tendency to “pucker” requires to be carefully guarded against. When conducting the experiments for the Conway and Britannia Bridges, this weakness was strikingly apparent, and was carefully considered; and as the strains in that of a ship and a monster tubular girder are analogous, it is necessary in both structures that the resistance should be clearly under-

stood, the two forces nicely balanced, and the tendency to buckle prevented.

To enable the practical ship-builder to acquire this knowledge, and become acquainted with the laws which govern iron structures of different forms, it will be necessary to investigate this question attentively, and endeavour to establish sound principles of construction in the minds of those who are entrusted with designs of such great public importance.

To construct a perfectly secure iron ship, every one of the transverse joints should be planed, in order that the ends of the plates may butt and form a solid joint. This connection is the more important, as the action of a vessel pitching at sea is a continued series of alternate strains of tension and compression. This motion is the most violent to which a vessel afloat is subject, and it is the most injurious to the structure. A vessel of war covered with armour plate, or a mercantile ship with a heavy cargo, plunges heavily at sea, and the waves meet her with violent shocks, so much so as to slacken her speed, and cause her to tremble or vibrate on the crest of the wave. This motion is somewhat analogous to that of rolling, but much more severe, as that part of the vessel which is left unsupported acts as a weighted lever on a transverse axis through the ship's centre of gravity, and thus produces severe strains at midships. By extending the weights or cargo in the direction of the bows and stern these strains are increased, and this, as a general rule, should be avoided by concentrating the cargo as much as possible at the centre of the ship.

Let us suppose a vessel in the middle of the Atlantic or Pacific Ocean having to encounter a rolling sea in a storm, where the elevation from the trough to the crest of the wave is 24 feet, and the distance from point to point 330 to 400 feet; and, supposing that these waves move at a velocity of 10 knots an hour, and we have a vessel, as represented in fig. 1, with two waves, one at the bow and another at the stern, and her midships

FIG. 1.

partially unsupported, as if two liquid rollers (if I may be allowed the expression) were passing at the above rate under her bottom. In this position the strains would have a tendency to crush the material composing the upper deck at A, and to tear asunder the hull or bottom

B. Hence the necessity for increased resistance in those parts. Reversing this position, and supposing that the liquid rollers or waves have passed from the bows and stern to the centre of the ship, and we have her balanced in the shape of a scale-beam as at fig. 2, with both ends only

FIG. 2.

partially supported. In this position the strains are reversed, and we have the crushing force along the bottom as at B, and the tension or tearing force pulling at A on the upper deck.

Assuming, again, that the wave has passed from the

centre of the vessel half-way to the stern, and we have the same forces continued, namely, the maximum of tension on the upper deck at the point A immediately over the apex of the surge, and compression at B below (fig. 3).

FIG. 3.

In these forms we have nearly all the disturbances and variety of strains, independent of rolling and wrenching, to which vessels are subjected when afloat. Under other circumstances, such as a vessel stranded on a lee-shore, beaten on rocks or sandbanks, similar forces of much greater intensity come into operation, and the only safeguard in these conditions is increased strength at midships and a sufficient number of water-tight bulk-heads, dividing the ship into five or six different compartments.

From the above it will be seen that alternate strains of varying intensity are continually in action during the time the vessel is plunging at sea with the whole of her cargo on board.

On the question of the strength of iron ships, we could

not have a more striking illustration of the disastrous effect of defective construction, than that which took place in the case of the Montreal Ocean Mail steamer *Jura*, only a fortnight ago, which, by some mistake of the pilot, ran upon the Crosby-spit, a narrow sandbank, at the entrance of the Mersey. She was running full speed at the time. The fore part of her keel became fixed on the bank, the stern hanging in deep water, and the result was she parted at midships, as shown in the sketch, entirely for want of a judicious application of iron stringers on each side of the upper deck, calculated to balance the area of the hull at midships, and to resist the force of tension which tore her assunder on the upper deck.

On this very important inquiry of alternate strains, we are fortunate in having before us a series of experiments on the endurance of iron-jointed beams subjected to these changes. Not exactly similar to that of a steam engine beam, but a less severe test, arising from alternately re-imposing and removing the load. This, it will be observed, was simply a constant change of tensile force in one direction, and compressive on the other, whereas that of a ship is subject to both tension and compression on the bottom and upper deck as she rises and falls upon the waves.

On referring to the experiments to which we have alluded, we arrive at this curious and interesting fact, that the joints of an iron riveted beam sustained upwards of ,060,000 changes of one-fourth the weight that would

break it, without any apparent injury to its ultimate powers of resistance. It, however, broke with 313,000 additional changes, when loaded to one-third the breaking weight, evidently showing that the construction is not safe, when tested with alternate changes of a load equivalent to one-third the weight that would break it.*

These results are probably not without interest as regards the construction of iron vessels, as they appear to be conclusive that time is an element in the endurance of structures when subjected to severe strains affecting their ultimate powers of resistance. It is difficult to determine or pronounce what is the correct measure of safety,

* Vide "Philosophical Transactions."

whether one-fifth or one-fourth the breaking weight, but we have sufficient data to be assured that every disturbance, however minute, in the molecular construction of bodies finally tends to their destruction, and it is only a question of time when rupture ensues. We may, however, be assured that a ship, as well as a beam, is practically safe for a long series of years when the strains do not exceed five tons per square inch upon the wrought-iron plates of which it is composed.

Dr. Rankine has investigated this question, and in a paper read before the mechanical section of the British Association for the Advancement of Science at Bath, entitled, "On some of the Strains of Ships," he states that in previous scientific investigations respecting the strains which ships have to bear it has been usual to suppose the ship balanced on a point of rock, or supported at the ends on two rocks. The strains which would thus be produced are far more severe than any which have to be borne by a ship afloat. The author computes the most severe straining action which can act on a ship afloat, viz., that which takes place when she is supported midships on a wave crest and dry at the ends, and he finds that the bending action cannot exceed that due to the weight of a ship with a leverage of one-twentieth of her length, and the racking action cannot exceed about ~~sixteen~~ one-hundredths of her weight. Applying these rules to two remarkably good examples of ships of 2,680 tons displacement, one of iron and the other of wood, described by Mr. John Vernon, in a paper read to the Institution of Mechanical Engineers in 1863, he finds the following values of the greatest stress of different kinds exerted on the material of the ship:—In the iron ship—tension, 3.98 tons per square inch; thrust, 2.35; racking stress, 0.975. It follows that in the iron ship the factor against bending is between 5 and 6, agreeing exactly with the best practice of engineers, and that there is a great surplus of strength against racking. In the wooden ship—tension, 0.375 tons per square inch; thrust, 0.293. Here the factor of safety is between 10 and 15, which is also agreeable to good practice in carpentry. As for the racking action, the iron diagonal braces required by Lloyd's rules would be sufficient to bear one-third of it only, leaving the rest to be borne by the friction and adhesion of the planking.

From these inquiries it would appear that the strains are considerable on an iron ship—that for tension being 3.98 or 4 tons per square inch; thrust, or compression, 2.35 tons; and racking stress, 0.975 tons; evidently showing that a ship labouring at sea is subject to severe tests of repeated strains, independent of shocks which may occur from displacement of cargo or waves of greater magnitude, which generally succeed each other at certain intervals in severe gales. But be this as it may, it is necessary to have iron ships securely and strongly built.

FLEXURE AND CRUSHING.—It has been ascertained that the effect of compression on any substance is to shorten its height and to enlarge its surface by increasing its bulk horizontally. Supposing, however, that the substance is confined and prevented from spreading in that direction, and it will then be found that the weight of one ton compresses wrought iron about $\frac{1}{10000}$ part of an inch; and in cast iron, which is much harder, we meet with this anomalous condition, namely, that a similar specimen is shortened or compressed $\frac{1}{10000}$ parts of an inch, being double that of wrought iron with the same weight. This arises, probably, from the porosity of its crystalline structure as compared with wrought iron, which undergoes a process of consolidation by hammering and rolling.

Another curious circumstance connected with wrought iron when submitted to compression is, that it will bear any amount of pressure provided it be sufficiently ductile. It, however, suffers distortion by a comparatively light weight, and its resisting powers are seriously injured with 12 tons per square inch. Beyond this it may be compressed to any extent, provided it be sufficiently plastic,

by enlarging its base and shortening its height till it becomes a perfectly flat plate. With 12 tons its elasticity is much impaired, and it takes a considerable permanent set, which increases as the square of the load, and in most cases, where these effects are important, it is desirable, if not absolutely necessary, to keep within the limits of its elasticity.

We have already seen that both the top and the bottom of a ship have to resist a force of compression analogous to that sustained by columns, and that being the case it is desirable that we should become acquainted with the resistances of wrought-iron of different forms in that direction. It is also necessary to ascertain the laws by which these resistances are regulated in the relative positions of the upper deck and the lower hull of a ship. Effectively to resist these forces, it is obvious that the covering plates below and the stringer plates above require to be stiffened, or, in other words, to convert them into a series of horizontal pillars, calculated to offer an equally powerful resistance to compression as they do to tension. It was for that object that the late Professor Hodgkinson undertook—in conjunction with the writer, when engaged in the construction of the Britannia and Conway bridges—a laborious series of experiments on the compression of wrought-iron plates and tubes which form the top of these immense structures. These experiments apply with equal force to the construction of iron ships as they do to tubular bridges, and we may therefore find it serviceable to offer a few remarks upon them.

In the earlier experiments it was found that round, square, and rectangular tubes, of a given length, presented nearly double the resisting powers when the same weight of material was applied in the form of a tube or cell than it did in the form of a solid plate. These facts were subsequently confirmed by Professor Hodgkinson's experiments, of which the following table is an abstract. (See Table, page 28.)

A plate employed as a pillar resists flexure in a much higher ratio than in the simple proportion of its thickness, such stiffness or strength being analogous to the transverse stiffness of a beam; hence, as in the beam, it will also be highly advantageous to distribute any given material in a pillar, in such a manner as to ensure the greatest possible depth in the direction in which it is liable to bend. Mr. Hodgkinson states that if the pillars are short as compared with their diameter, such precautions are unnecessary, the cubic inch of wrought iron cannot be put in better form, but if it were rolled into a very long and very thin plate, one inch broad, and placed on edge, the smallest force would bend it. If we shorten this thin plate by increasing its thickness, but maintaining the same height of one inch, we shall increase its resistance to flexure in proportion directly to the cube of the thickness, and in proportion inversely to the length, since the length will diminish in the same proportion as the thickness increases, therefore the strength will increase directly as the square of the increasing thickness, or inversely as the square of the decreasing length, until the plate arrives at such a thickness that it will fail partly by crushing. This law will now begin to vary as we go on increasing the thickness at the expense of the length; and ultimately, as we approach the cube itself again, the strength, instead of varying as the square of the increasing thickness, will cease to vary at all with the thickness; its strength will, therefore, have varied during these changes, as every power of the thickness between 0 and the square of the thickness, while the resistance itself would be represented progressively by every quantity between 16 tons and 0, the quantity of material or section and height having remained constant, so that n -square inches of sectional area on the top of a tube may resist any compression between 0 and $n \times 16$ tons, according to the form in which it is applied.

We should thus use the thickest plates we can get for the top of a ship or a tube, until their thickness was such that any variation in the thickness causes no corresponding variation in their resistance to compression; beyond this we get

RESISTANCE OF RECTANGULAR TUBES, ALL TEN FEET LONG, TO A FORCE OF COMPRESSION IN THE DIRECTION OF THEIR LENGTH.

no further advantage. If, however, we are compelled to use thin plates, we should arrange them so as to ensure depth to resist buckling. If one cubic inch, when rolled out into a long strip, so as to fail by flexure, were, for instance, formed into corrugations, it would in this form support considerably more than in the form of a straight plate,

FIG. 4.

for instead of being a mere line in section, with no depth, it would now possess a depth equal to the versed sine of the corrugations, or equal to the distance between each convexity; and in this corrugated form we should attain the maximum resistance to pressure, viz., 16 tons, with our plates much thinner than when used straight. The depth would be still further increased if we folded our corrugated plate round upon itself, so as to complete a series of tubes, taking care to unite carefully the points of

FIG. 5.

contact. There are numberless familiar examples of stiffness obtained by such method of construction. An ordinary paper fan, and many household articles in tin, though constructed of thin and pliable material, are extremely strong and rigid from the depth acquired by the bending of the material. The domestic tea-board and dust-shovel are striking examples. It thus becomes a question, with a given section of material of given thickness, how to construct the strongest form of pillar or a series of pillars to resist crushing, and how near we can with this form approach to the limit of 16 tons per square inch.

Since a flat plate, for the reasons explained, will bend sooner than a curved plate, it would be concluded, naturally, that a round tube, of moderate dimensions and of given thickness and section, would be a stronger form than the same plate in a rectangular form, in which the resistance to crippling must depend solely on the four angles; and since the rigidity afforded by the angles is extended throughout the four sides of a rectangular tube, in some manner proportionate to the distance from the angles, it would be concluded that a square tube  would be stronger than a rectangular tube  constructed with the same plate, inasmuch as the central portions of the longer sides of the rectangle will be less maintained in form on account of their greater distance from the angles; similarly increased strength might be expected from this form  These assumptions were all submitted to experiment and confirmed.

For this purpose a number of tubes or cells of wrought-iron were constructed, all ten feet long, and either four or eight inches square, or of rectangular form about four by eight inches; their ends were perfectly flat, and they were compressed, by the intervention of a lever, between two parallel discs of steel, with arrangements for maintaining the pressure perfectly vertical, the cells being supported laterally. The direct object was to ascertain the value of each particular form of cell, and to ascertain the resistance per square inch of section in each case. The lateral dimensions of these cells are so large, that with a length of ten feet the pillars were not destroyed by flexure as in a long pillar, but by absolute buckling or crushing; the strongest possible form should, therefore, give about 16 tons per square inch of section.

Similar experiments were then made with circular cells, under precisely similar circumstances for comparison. The cylinders varying from 1½ in. to 6 in. in diameter; the diameter being so small in some cases as compared with the length, some of these pillars failed by

flexure, and followed the laws of long pillars, the resistance increasing nearly inversely as the square of the length; but where the diameter was six inches, the length being ten feet, flexure could not take place, and the cells filled by buckling or crushing, as in all the rectangular pillars, and in such pillars the strength is independent of the length.

To show how the failure in the rectangular and cylindrical tubes took place, the annexed drawings, as represented by Figs 6, 7, 8, and 9, may be useful.

From the foregoing researches it will be observed, that in order to attain the maximum powers of resistance to compression in the use of iron plates in construction, that the square box with thin plates next to the plate itself is the weakest experimented upon; the next in the order of strength is the rectangular form with a division across the centre as at c,  but the best distribution of the material is in the cylindrical form. This latter cannot, however, be accomplished conveniently in ship building, but the rectangular or cellular construction is applicable in all cases where resistance to compression as well as tension is required in the hull and upper decks of vessels.

LASTLY, ON THE DISTRIBUTION, STRENGTH, AND VALUE OF WROUGHT-IRON PLATES AND FRAMES AS APPLIED TO SHIPS AND OTHER VESSELS.—In this department of inquiry, we have not only to consider the nature of the strains to which the sides and other parts of a vessel are subjected, but we have to determine the distribution of the material in the different parts of the vessel, so as to establish as nearly as possible perfect uniformity of strength. What we mean by uniformity is, that the resistances in any one part of the vessel should be proportioned to the strains on any other part, and that no waste of material should take place beyond what is necessary to maintain the balance of the opposing forces of strain and resistance. In our endeavour to determine the superior value of iron as a material of which vessels should be constructed, we have not entered into the question of distribution. This is, however, one of the most important elements of construction, and in order to approximate as closely as possible to uniformity of strength, we have to apply the material in such forms and positions as will effectually resist all the various strains to which the vessel is subjected.

It will be observed, that in the preceding investigation we have invariably viewed the question of vessels as they are now built, being subject to much severer strains than

formerly when built of wood. The present class of steamers are nearly double the length that they were formerly as sailing vessels; and the depths are much less in proportion, so as to render their powers of resistance to the action of the sea less than one-half that which would have been the case had the form of construction been upon the old principle. This being the case, a series of strains of double intensity are brought into existence, and these have to be provided against if we are to have safe vessels on the new principle of construction.

All these changes are elements of weakness unless met by an equable distribution of the material, and it is on this principle that we have treated the new build of vessels as hollow girders. Let us, for example, take a first-rate ship of war as built seventy years ago, such, for instance, as the *Victory*, and we have:—

	feet.	in.
For the length between the perpendiculars...	260	0
Breadth of beam	60	1
Depth	58	10

This according to formula $W = \frac{ade}{l}$ would—if built

of iron and duly proportioned with sectional areas of 800 square inches, and if suspended on two points, stem and stern, sustain a load in the middle of 9,785 tons, or 19,570 tons if equally distributed.

Taking the same sectional area, and applying it to a vessel similar to the *Warrior*, and we have, with the same areas and the same constant 60, the decks being duly proportioned to the bottom,

	feet.	in.
For the length	380	0
Breadth	58	4
Depth	42	0

Hence $W = \frac{800 \times 42 \times 60}{380} = 5,805$ tons as the

breaking weight in the middle, or 10,610 tons equally distributed, which is little more than half the strength of the former. From these facts it will be seen that we require an increased sectional area of 675 square inches in addition to balance the resisting forces of the two ships, which evidently shows that, increasing the length and diminishing the depth, the present build of vessels, when constructed of the same material, requires an increase of strength in the ratio of 1475 : 800 or as 1 : .542. But this is not all, as we find from experiments on the effect produced on wrought-iron when subjected to alternate changes of load, that to build a durable vessel we should have to calculate the sections of the hull and upper deck, and to render it endurable under the varied strains to which it is subjected these should not, on the sectional area, exceed five tons per square inch.

A vessel thus constructed would, in our opinion, be perfectly safe under every condition when exposed to the action of the sea, but, if stranded upon a rock or shelving beach with coal and cargo on board, she would be severely tried by the force of impact when continuously rising and falling, and subjected to the influence of a tempestuous sea. But even in this precarious position it is very questionable whether or not she would go to pieces. On the contrary, we are of opinion, if constructed with watertight bulkheads, strong longitudinal keelsons, and double bottoms, that in nine cases out of ten she would hold together, and save the lives of all on board.

In the distribution of the material there is another consideration of great importance, and that is, that in all bodies in the form of beams, whether hollow or solid (they follow the same law as regards a transverse strain), the strains are always greatest in the middle, and progressively diminish to the points of support at either end. These facts are self-evident, and show in the case of an iron ship that the same thickness of plates is not required when working from the centre at midships to the stem and stern. In fact, they should taper and be reduced in thickness in the

ratio of their distances from the centre till they reach the extremes at each end. Theoretically this is true, but in practice we have to consider how much the thickness can be reduced without danger to the structure, and in these we may here observe that the reduction should not exceed one-third between the centre and the two extremes. Or, in other words, if we assume the strakes or sheathing plates of the bottom and round the bilge to the height of the interior floor, or one-fifth of the depth, to be $\frac{1}{4}$ th of an inch thick, it then follows that their thickness may be safely and progressively reduced to $\frac{1}{8}$ ths thick towards the bow and stern. The same reduction to $\frac{1}{8}$ ths thick may be made from that point, one-fifth of the depth, to the neutral axis of transverse strains, or about half-way up the ship's side, when they should again increase to $\frac{1}{4}$ th thick on the top strakes at the deck, on each side, where they have to perform the office of stringers under the action of the two forces of tension and compression.

From these remarks it is obvious that a careful distribution of the material is a desideratum of considerable importance in shipbuilding, and although it may be necessary in some constructions to make deviations, it is nevertheless essential that the law of strains should be carefully observed and weak parts effectively guarded against.

It will not be necessary in this communication to give drawings in illustration of these statements, as from other data the question may be rendered sufficiently explicit to enable the iron shipbuilder to proportion the parts in the ratio of the strains, and to afford to the ship, as a whole, ample powers of resistance to the forces by which she may be assailed; care however being taken to provide for wear and tear, oxidation, and all those other influences which tend to weaken the ship.

I would have entered more on this question, but I have already exceeded the limits of an ordinary paper, and must reserve for some future occasion the further development of a subject of such deep interest in connection with naval construction. I may, however, state in conclusion, that the iron navy of this country is destined to take the place of the "Hearts of Oak," and become—as many now living may hope to see it—the dread of our enemies, the bulwark of commerce, and the harbinger of peace.

DISCUSSION.

Capt. HENDERSON said—As an old sailor he wished to offer some observations on the construction of ships, but especially of light-draft steamers for India, in which he had had some twenty years' experience, and gained much information from Mr. Fairbairn. With reference to the diagram on the wall of a box-girder or deck-stringer, by which Mr. Fairbairn strengthened the upper decks of ships, he (Mr. Henderson) stated that he had practically adopted this system in river steamers of the Assam and native types, the bottom forming the bow, with seven keelsons, on the bow-and-string principle of construction. The Government sloop steamer, built for the Indies, was on the reverse, *i. e.*, the bottom formed the string, and the arched girder the bow above; and on being tried on the Thames in 1861, with full power of engine, the bottom bent downwards. The arched girder was strengthened before shipment to India. Similar trials on the Thames of the *Assam Nautilus*, also built by himself (Capt. Henderson), proved her speed and steering power; and her strength had been tested by grounding on the banks of the Thames, and lying across dock gates, with 40 tons on board.

Mr. JOHN HAWKSHAW remarked that little room was left for observation on the paper, because it dealt so largely with the elementary principles of construction which were generally known and acknowledged. He should, perhaps, best show the extent to which he agreed with his friend, Mr. Fairbairn, by mentioning the principal point on which he differed from him. The paper advocated what he would call the old-fashioned principle of putting to-

gether iron plates by punching the rivet holes, as better than that which he believed he (Mr. Hawkshaw) had adopted, perhaps more extensively than any other engineer, *viz.*, by drilling. He differed entirely from the views laid down by Mr. Fairbairn in this paper. He (Mr. Hawkshaw) had used the method, which his friend Mr. Fairbairn must permit him to call the sledge hammer principle, for many years, and he had come to the conclusion that this punching principle, whether in ship-building or bridge-building, or in any other of those different constructions to which iron was now applied, was very faulty. He (Mr. Hawkshaw) had for some years past adopted the principle of drilling the plates, and he had no hesitation in saying, from his experience, it was greatly superior to the work which was produced by punching. He had no hesitation in saying that if the Britannia-bridge, instead of being put together by punched plates, had been put together by drilled plates, there would have been a better result by 20 or 25 per cent. There was considerable difficulty in the first instance, when he required manufacturers to drill instead of punch, *viz.*, the increased cost which the manufacturers thought would be entailed by this plan, but such was not proved to be the case. Gentlemen who had constructed iron work for him, and who had adopted the principle of drilling instead of punching, had stated publicly, and he (Mr. Hawkshaw) was therefore justified in asserting, that having once gone to the expense of providing drilling machinery, it was cheaper to drill than to punch. He had had machinery constructed which would drill from 30 to 60 and even 80 holes at once, and the work obtained by that method was very superior to that on the old plan. A simple experiment would show this. Take a number of plates that had been riveted together, having been previously drilled, and saw them through the line of the rivets, and do the same with a similar number of plates riveted after being punched (and he had tried it himself), and it would be found that in the one case the line of demarcation between the rivet and the plates could scarcely be traced, while in the other numerous interstices not filled up between the rivet and the plates were frequent. If they had merely to rivet two plates together by punching, no doubt by adopting the principle of compression, which he agreed with Mr. Fairbairn was better than the hammer, these interstices might be filled up; but when a large number, say ten plates, had to be put together, there the punching system failed, whilst with the drilling system the ten plates could be put together with the same perfection as two. As that was the only point on which he differed from the views expressed in the paper, he might be excused calling attention to it. With regard to the paper generally, it laid down a great number of principles which were universally acknowledged, but it did not, as it appeared to him, touch that very difficult question as to what was to be the mode of construction for iron ships of war. He had himself, as far as he had had time and opportunity, given considerable thought to that question; and he was free to confess that the more he thought about it the more he found it surrounded with difficulties. He, therefore, could not agree with those gentlemen who thought that by this time somebody or other ought to have determined what was the best form of construction for a ship of war. Before they determined that question, they must settle previously which of two principles was to be adopted, *viz.*, whether the armour of a ship was to form part of and conduce to the strength of the ship, or whether the armour of a ship should be treated as something extraneous to the ship, to be placed upon it or hung about it, to be donned or doffed as occasion required. Until these questions were answered he did not see how they were to arrive at the proper form of construction for ships of war. So far as he had had opportunity of judging—and he had seen *La Gloire*, as well as the *Warrior* and other specimens of war ships, and the various targets that had been experimented upon at Shoeburyness—he thought

there was a confusion of ideas as to what was to be aimed at. It did not appear to be settled whether the armour should form part of the ship, and therefore add to its strength, or whether it should be something merely to defend the ship itself. This must, however, be settled before ships could be built on an intelligible principle. He gave this opinion deferentially, because it was a very difficult subject, and possibly never would be solved without the terrible experiment of a great war. So far as he had been able to come to a conclusion on the subject, he did not see why the armour of a ship should not be made conducive to its strength. He was honoured by the committee appointed to consider that subject by being requested to construct what was called a target. It was not in fact a mere target he had constructed, but a combination of iron plates, to illustrate his own views of war-ship construction. He stated distinctly, in writing to the committee, that it was not put forward simply as a target, because if they wanted a target, a thing merely to resist shot, it was the simplest of all things to make. All they had to do was to make something as like an anvil as they possibly could, a large lump of iron of the best texture. This would doubtless resist shot. But the problem they had to solve was how to introduce this enormous mass of iron into the fabric of the ship, and whether it could not be conducive to the strength of the structure. This was not easy to do. The question, however, must be solved before they could set about building a ship of war.

Mr. JOHN GRANTHAM would take the liberty of intervening between his two friends, Mr. Fairbairn and Mr. Hawkshaw, on the question of riveting, a subject to which he had given great attention, and on which he had lately read a paper before the Institute of Naval Architects. He did not wholly agree with Mr. Hawkshaw on all his points. He believed that in bridge-building and all straight structures it was not difficult to drill the holes successfully, and much better than if they were punched; but the paper dealt principally with ship-building, and there a different condition of things arose. They had scarcely any straight plates in a ship, but they were for the most part of a curved form. The plates had to be applied singly, one after another, under difficult circumstances, and hence drilling could not be readily performed with success, and be considered it objectionable. In putting together two plates no advantage could be claimed for drilling, for when the two plates were put together, in drilling a burr formed, and the oil and dust from the outer plate fell in between the two plates; that accumulation and the burr had to be removed, and for this purpose the plates must be separated; and he could therefore say, as far as his own experience went, that Mr. Fairbairn's remarks as applied to ship-building were correct; but with regard to straight girders, or bridge work, with which Mr. Hawkshaw had been principally engaged, drilling was by far the best process with a number of plates. There was no question that the holes could, by drilling, be made more accurate than by separate punching. He had hoped that the paper would have dealt at greater length with some of the points of importance occupying public attention, and that it would have entered more largely on the question of the construction of ships of war. He thought the paper had not gone sufficiently into that subject. The great question of the day to be determined was, were our ships for the Royal Navy to continue to be built of wood, or were they to be built of iron? In the merchant navy this question had long been settled. It had long been settled that a ship was a girder in principle, and the nearer they approached to it the better. It had long since been settled that a ship must be strongest in the centre and lightest in the ends, but they had not yet settled whether a ship of war should be built of iron or wood. Some practical men had gone halfway in this matter, by introducing iron in one part and wood in the other. In his judgment that was an unfortunate combination. If iron was good, let it be iron; if wood was good, let it be wood—but do not combine the

two together in the unfortunate way in which he thought it had lately been done. The great difficulty with regard to iron ships had not arisen upon any difference of opinion as to strength—that had been settled thirty years ago. The durability of an iron ship had also been long since settled. The commercial advantages of iron in ship-building had been long since acknowledged by the universal testimony of the mercantile community; but there was one question which was not yet settled, and that was the great question of fouling. The whole navy of Great Britain at the present day he believed would have been built of iron if the difficult subject of fouling had been got over. That was the real mischief now hanging over iron ships. Referring to another part of the subject, whether the iron plating was to be made part of the strength of the ship or not, they must determine whether the rest of the structure was to be of wood or of iron? If they had wood, all they could do was to hang the plates on the sides as a mere protection. If they made the rest of the structure of iron, then came the question whether the armour plating might not be made part of the strength of the ship? Why should they not make effective use of this ponderous protecting mass of iron in giving strength to the ship. Why should it be thrown away? Why should not the whole ship be built of iron? Were they still to adhere to that which the mercantile community had long condemned, and still cling to wood in the construction of the hulls of the ships of war? More especially, considering that all war ships were built for steam engines, for which a wooden structure was unfitted. Then came the question of fouling. He had been for 40 years connected with shipbuilding, and for 30 years had given his attention to the subject of fouling of ships, and he ventured to assert that, in spite of all the inventions and suggestions which had been brought before the public, they were no forwarder at this day than they were 25 years ago. He would call attention, however, to the fact that there were ships built half of iron and half of wood, but not in a manner adapted for some of our vessels of war. The ribs and many other parts were of iron; but the ship was afterwards covered with wood. Those ships had been found the best for tropical climates as regarded the fouling of the bottoms. They possessed many of the advantages of iron ships, and got rid of the evil of fouling. Ships of this class had been found exceedingly serviceable. He, however, would suggest an additional step in this direction, and that was to build the whole ship of iron, and afterwards sheath her with wood, and copper her under the water. They had proofs that this system was excellent; it prevented fouling, and secured all the practical advantages of an iron ship. He believed if this had been done years ago there would not have been a single wooden ship in the navy, and the whole contest would have been at an end.

Mr. ROCHUSSEN said, as he was connected with several continental iron and steel manufacturers, he might be allowed to say a few words on the strength of iron, the use of which, as a material for ship-building, together with the employment of steam as a propelling power, was largely extending, not only in this country, but also in France and America. The average tensile strength of the ordinary iron used for ship-building was 32½ tons in the line of the fibre, and 31½ tons across the fibre. He had with him the details of experiments made by Mr. Fairbairn, which corroborated those figures. He thought that steel might with advantage be introduced into plates for ships; and it was worthy of consideration how far this lighter material might be beneficially employed. The steel might be rolled. It was simply a question of power. If, by so doing, 400 or 600 tons weight could be saved in the plating of a ship like the *Warrior*, it would afford great facilities for carrying a heavier armament.

Captain SELWYN, R.N., would say a few words on the question of strains to which ships were subject at sea. The strains were not as pointed out by the author of the paper

though he (Capt. Selwyn) was aware that such were in accordance with the views generally held, which supposed a ship being possibly suspended between the crests of two waves. Those who advanced that idea seemed to forget that which was sufficiently patent to all seamen, viz., that a ship in such a condition immediately sank in the water to a medium line of flotation. There were only two circumstances under which the waves could so operate: one was when from a gale or swell at the stern the waves came in that direction, and the other was when a vessel was driven by a gale against a head wind. Every good seaman knew it was madness to drive a vessel ahead against a heavy gale of wind, for if they did so invariably the bows shot out 50 or 60 feet unsupported in the air. Under those circumstances strains were brought on the vessel such as nothing ever built by human hands could hope to stand against. A good seaman would either lie-to or make only moderate speed. It was true in modern days the outside pressure for quick passages sometimes led seamen to act against their better judgment, but they knew they did so at the risk of the vessel breaking up. He had spoken of the sea coming up by the stern, and under such conditions no such strain as had been described need be feared. The vessel, it must be remembered, was going ahead at a given rate, and the wave and undulation—for he made a distinction between the two—the wave rose and fell, but its particles were not propagated forward as fast as the undulation. Those waves coming on the stern found the vessel progressing in their own direction, and they then only gently lifted the stern and passed under the ship, not causing any great strain, and seldom pooping the vessel unless some false manoeuvre had been performed. With regard to the question of thickness of plates for ships, he begged Mr. Fairbairn to consider whether or not he could safely recommend increased thickness in the midships, and decreased thickness at the ends, considering that it was not so much the effect of the strains that was to be feared as the results of concussion when a vessel grounded on a bank and then lifted with the sea. After the battle which had been so severely fought between wood and iron, compromise was a very agreeable thing to hear of, but he was afraid that Mr. Grantham had not sufficiently considered the effect of shells in his recommendation of a sheathing of wood, which he was sure would be stripped off in ten minutes after the vessel had been in action, or would be set on fire by shells; and even if the wood were rendered partially incombustible, as no doubt it might be done, the smoke from the smouldering wood would be sufficient to render the vessel untenable.

Mr. GRANTHAM said the wood sheathing would only reach to the edge of the armour plates, several feet below the surface of the water.

Captain SELWYN added that trial had been made of that plan, and it did not answer when armour plates were concerned. He had read a paper before the Institute of Naval Architects on the galvanic action of the bottoms of ships. It was proved that galvanic action could not be interrupted; as it went on between the iron and copper and salt water, either by strips of intervening material or otherwise, and in spite of every device hitherto thought of. It did go on, because though there might not be metallic conduction, yet there was conduction through the water which was sufficient to set up and carry on galvanic action. The effect of this was accumulated at the point of contact with the armour plates. That action was not less to be feared in the lighter construction for mercantile purposes, and the rivets constantly dropped out, as in the case of the *Harbinger*. In some instances the galvanic action had been stopped by protecting the bottom with asphalt, and in one case by a coating of brickwork covered with asphalt. With respect to the bricks, they contributed nothing but an objectionable weight, and he thought a better material than asphalt might be

employed for preventing the salt water from acting as a medium of setting up galvanic action. These matters were so important in the advanced state of shipbuilding that calling attention to them was not out of place.

The Duke of SOMERSET, in proposing a vote of thanks to Mr. Fairbairn, said he was sure those who had heard the paper, and the discussion that had followed on it, would admit that very many important questions had been raised. He further thought it would be admitted that the Admiralty had at least been placed in some difficulty, when called upon, at short notice, to provide the best ships of war. They had been told that evening that it was very difficult to say what was the best possible ship of war, by persons who had been inquiring into the subject for many years. They were told that the Admiralty ought to provide ships of the best iron, and projectiles of the best steel, and yet, when they came to inquire as to what was the best iron and the best steel, there was no conclusive knowledge to be obtained. Dr. Percy, in the preface to his book on Metallurgy, stated that as regarded the chemical nature of iron, our knowledge was very imperfect; and as to steel, still more so. Then they came to the mechanical tests: and the question then arose how far did the tests injure the iron? That question was very important, and one which he did not think had been clearly settled. He wanted to know how far they could proceed in testing without injury. It was proposed in the paper that iron vessels should be tested. Would they for that purpose place the two ends of a vessel in the position represented in the drawing, in order to see whether or not she would break; or would they test the plates? Would such tests, if the vessel withstood them, leave the ship or plates uninjured? and could they be sure that no injury had taken place? With regard to the testing of chain cables also, the same question arose—were they quite sure, in the testing of chains, how far they might test them with safety? In regard to the proving of cannon, again the same question arose—their testing might injure the metal. As to steel projectiles, how were they to test them? Were they to fire against iron plates every time? Were they to break a number of plates in order to break the projectiles? Then as to the construction of the ship of war. They had been told that the Admiralty were advocating a wrong principle, and that they ought to make up their minds and build entirely with either all iron or all wood; and another gentleman had told them he had successfully built iron ships, and covered with wood. In attending the meeting that evening, he was in hopes of learning that some of these conflicting questions were about to be solved, and that he should have gone to the Admiralty in the morning, and informed his colleagues that the whole question had been set at rest. But he was still left in difficulty. They were told that iron was the best material for resistance, and that they ought not to combine iron and wood together. That had been the opinion of the Admiralty, and it was the opinion also of Mr. Fairbairn. They tried experiments at Shoeburyness, but Mr. Fairbairn had told them they must put a certain quantity of wood behind the iron, in order to obtain an effective resistance to shot. This evening, however, some gentlemen had told them not to use any wood at all. This showed that the subject was still surrounded by numerous difficulties. He would say he was delighted to have heard this discussion, and he hoped they should at some future time have another paper devoted to the consideration of some one or two of the points on which they desired to be enlightened. Instead of entering into general questions let them take up one great question and see if they could arrive at satisfactory results upon it. In the meantime he had great pleasure in proposing a vote of thanks to Mr. Fairbairn for his very able paper.

The vote of thanks having been passed,

Mr. FAIRBAIRN said the paper was not intended to be limited to the question of armour plate and ships of war,

but it applied also to vessels for commercial purposes. The main object was to show how, both in the navy and mercantile marine, the material could be best distributed in order to obtain strength in the ship. With regard to riveting, he was quite aware there was difference of opinion; but his own feeling was, where riveting was well executed, they could not have a better test of the quality of plates than by punching, and, where the holes were well punched, he preferred them to the drill, as he found that in drilling the holes were not always exactly coincident. Then as regards ships of war, he hoped on a future occasion to bring forward another paper on this subject, which he trusted would lead to a discussion that would realise to some extent what the Chairman had suggested as important, viz., something like certain information for the Admiralty to rely upon in the construction of ships. He should do his best to accomplish that object, and from the experience he had had he might state that he was satisfied iron was a better material than any other for building ships either for war or mercantile purposes. Under all these circumstances, he hoped the Admiralty would persevere in what they were now doing in the construction of iron ships. On the question of armour plates, he would say, if they were to have 300 or 400 pounder guns it was a question with him whether it would not be better to be without armour plates altogether, and let the shots go right through, because they were limited to a certain thickness and weight of plates; and if they were to cover vessels from stern to stern, and five feet below the water line, they would not be able to carry plates that would resist those large guns. If that description of artillery was used, his opinion was they would have a more secure and better navy without the iron plates than with them.

The Secretary called attention to some photographic copies of engineers' drawings, lent by Mr. W. Willis, of Bath-street, Birmingham. By means of a photographic process, the details of which are not yet published, copies of drawings can be made rapidly and cheaply of the same size as the original. The original drawing is in no way injured by the process, and the copy is produced by simple superposition over the chemically-prepared paper, and is a positive copy direct without the intervention of a negative.

The Secretary also called attention to a model of a tilt hammer, moved by means of a knee joint, driven by direct action of a steam piston.

DUBLIN INTERNATIONAL EXHIBITION, 1865.

The Committee of the International Exhibition for 1865, have great gratification in publishing the following correspondence, conveying Her Majesty the Queen's gracious assurance of support to the undertaking:—

Dublin Castle, Nov. 19th, 1864.

MY DEAR DUKE,—After the interview I had the honour of holding with the deputation representing the Committee of the Dublin International Exhibition for 1865, I wrote to Colonel the Hon. Sir Charles Phipps, submitting the request that her Majesty would be graciously pleased to allow the Exhibition to be placed under the Royal patronage, and your Grace will be gratified to learn, from the enclosed correspondence, that this request has been most promptly complied with.—I am, yours very faithfully,

(Signed), ROBERT PEEL.

His Grace the Duke of Leinster.

Dublin Castle, Nov. 15th, 1864.

MY DEAR SIR CHARLES,—A deputation comprising the Duke of Leinster, Sir George Hodson, Bart., Sir R. Kane, Mr. Dargan, and several other members of the Committee of the Dublin International Exhibition for 1865, have just had an interview with me for the purpose of conveying the expression of their hope, through their Chairman, the Duke of Leinster, that her Majesty would be graciously pleased to allow the Exhibition to be placed under her Royal patronage.

From the enclosed prospectus it will be perceived that the enterprise is no longer of a purely speculative character, as it promised to be if it continued in the hands of the directors of the Winter Garden Company.

That Company has now nothing to do, as the Duke assured me, with the undertaking, and indeed many of the names on the Exhibition Committee are a guarantee of the respectability and public spirit which has been elicited in support of the movement.

I hope it will not be considered that I have gone beyond my duty in venturing to request that you would take a fitting opportunity of submitting this request for the patronage of the Queen to the notice of her Majesty, and there can be no doubt her gracious compliance would not only be most valuable to the prospects of the Exhibition, but that it would have the effect of giving a salutary impetus to the spirit and loyalty of all who are interested in the welfare of this country.—I am, &c., &c.,

(Signed) ROBERT PEEL.

Col. the Hon. Sir C. B. Phipps.

Windsor Castle, Nov. 17th, 1864.

MY DEAR SIR ROBERT,—I have had the honour to lay before the Queen your letter of the 15th inst., and the objection, to which on a former occasion I alluded, having been removed, I have received the commands of her Majesty to say that she is happy to be able to accede to the request contained in your letter, and to sanction the announcement of the Dublin International Exhibition as under her Majesty's patronage.

The Queen wishes the promoters of this patriotic undertaking every success.—Sincerely yours,

(Signed) C. B. PHIPPS.

Right Hon. Sir R. Peel, Bart.

Fine Arts.

EXHIBITION OF INDUSTRIAL ART IN PARIS.—This exhibition, which is now open in the Palais de l'Industrie, in the Champs Elysées, and which will continue so until the end of the year, is got up by one of the societies formed to aid the progress of art as applied to industrial purposes, and embraces specimens of the ingenuity of the past as well as of the present time. There was some delay in completing the arrangements, but at the present moment, although the collection is not large, it presents considerable interest. It occupies the whole of the central portion of the building, which is laid out as a garden, and all the objects are seen to the greatest advantage. The principal objects are contained in three large square pavilions, which occupy the centre and two ends of the garden. That in the middle contains some remarkably fine specimens of galvano-plastic work from M. Oudry's works, at Auteuil, where the great fountains, candelabra, and other objects for the city of Paris, are submitted to the electro process, and of which we gave a report from personal inspection in the pages of the *Journal* some months since. The most conspicuous specimen in M. Oudry's collection, is a reproduction of an alto-relievo from the triumphal arch of Constantine; this specimen of galvano-plastic art is no less than twelve feet high and nearly nine feet wide, and weighs nearly four thousand pounds English. The mould was taken in gutta-percha, from a plaster cast. This noble work is surrounded by a fine collection of electro bronzes—statues, statuettes, busts, and ornamental works, iron castings covered with copper by M. Oudry's peculiar process, specimens of plate rolled after deposit, spikes and nails for ship-building covered with a thick coat of copper, and other similar objects; also a number of articles painted in imitation of bronze with M. Oudry's peculiar bronze pigments. A second pavilion contains a most remarkable collection of antique objects of art industry from the celebrated museum of M. Le Carpentier, whose antiquarian wealth approaches that of M. Sauvageot, whose collection is new in the museum of

the Louvre. The selection lent by M. Le Carpentier to the exhibition contains specimens of almost every kind, from the carved runic staff to the royal game of geese, which Louis XIV. played at when a child (this latter is, however, the only object not of importance in an artistic point of view). The articles are of all ages and countries, and include works of metal, wood, and ivory—jewellery, china, faïences, enamels, terra-cotta, and embroidery. The metal work and carvings are, perhaps, the most remarkable of all, but the whole collection is extremely choice; the case of French enamels is especially noticeable, and some of the small arms of the best Italian period are very beautiful. Amongst the iron work is a shuttle, pierced and engraved most admirably—the elegant instrument with which some aristocratic Ariadne of the fifteenth or sixteenth century made the mantle of her liege lord. The expenditure of so much art on such an object marks curiously the change that has come over the habits of civilised people. The collection of retrospective art includes contributions from other virtuosi, and also from dealers in antiquities. The third pavilion covers a selection of fine specimens of modern art, made by the society from amongst the objects sent for exhibition; and each visitor on entering receives a printed ticket, which entitles him to a chance in the lottery which is to take place at the conclusion. It is fair to mention here, seeing that the objects of the society are purely patriotic, that the price of admission is half a franc on ordinary days, one franc on Friday, and five sous on Sunday. The exhibition, happily, does not contain a mass of the common *articles de Paris*; almost every stand has something in the way of novelty or improvement to recommend it, at any rate the exceptions are the minority. The class of wares best represented, perhaps, are faïences; there are some very beautiful specimens of ornamental porcelain, but the fashion of the moment is for earthenware, and naturally, the manufacturers are making great efforts to rival the productions—now so well known here—of Minton and other English makers. French ornamental wares of this class are not remarkable for colour; in this they are far behind Staffordshire. But the Parisian and other potters are making great strides in the production of panels and other pieces of ware for decorative purposes. The greater portion of these are imitations of Della Robia or other ware, the best are produced after original designs in the flat, somewhat affected, but graceful manner of Hamon, who himself has not disdained to lend the aid of his pencil, as Flaxman did, in the potter's service. The introduction of figures and landscapes on faïence slabs, in carved frames, has recently, may be parenthetically observed, become quite the fashion in the houses of the rich in and near Paris; and, in some instances, similar ornaments have been introduced into halls and vestibules and exterior walls, and with charming effect. The number of exhibitors in this class is not great, and when we mention A. Jean, who has a house in London, Deck, A. Gouvion; Masson, late Ollivier, established in 1742; Devers, an Italian; and Collinot and Co., all of or near Paris, we believe we have exhausted the list. (We may here note that there is not yet any catalogue of the exhibition.) Messrs. Collinot present a novelty in what is called *émaux cloisonnés*, and have covered their process by a patent; the designs, besides being slightly raised above the ground of the vase or other object, are marked by a very decided outline, hence the name selected for this new style of ornamentation. It is worthy of remark that the makers of porcelain and other fixtile ware have of late borrowed the very artistic habit of the Chinese, in mounting their best pieces on wooden stands carved in appropriate forms. It is marvellous how much more appearance of value a beautiful vase acquires by this treatment. Another sign of the time is to be seen in the iron works in this exhibition, which includes some very fair examples of pure hammered work as applied to the furniture of fire-places, lamps, and other domestic objects; some mere reproductions of the antique, others exhibiting truly

artistic taste without conventionality. We can no more expect *repoussé* work to replace casting and other modern modes of ornamentation than we can look for the resuscitation of the post-chaise in competition with the railway, but the hammering of iron, or other metal, into graceful forms is so high a branch of industrial art that it is pleasing to find it not quite neglected—especially when we take into account its unrivalled effect. The exhibition is decked with some very fine specimens of tapestry from the Gobelins, Aubusson, and other looms, and in juxtaposition with these semi-artistic productions, are some very good specimens of the machine-made carpets and tissues of a company established at Meaux. Among the miscellaneous objects is a new kind of fuel, composed of tan and coal-dust, recommended for all kinds of fire-places, but which seems to have slipped by accident into an exhibition of industrial art; a system of lighting establishments by means of petroleum oil forced through pipes of small diameter by means similar to those used in the moderator lamp; and a new bathing machine, or boat, which has quite charmed the Parisians. This last novelty consists of a very light frame or basket, rendered buoyant by means of cork or other floats, and propelled by a screw; the bather lies at full length, with his head on a pillow, and works the propeller by means of a winch; and, as the axis of the screw is jointed and provided with discs, against which he places the soles of his feet, he can guide his bark wherever fancy directs. Some of the *Beigneuses*, as these new toys are called, are floated by means of four or more silvery-looking swans, and have been dubbed Leda's cars. The *Beigneuses* promises to be a success, as it is already being made the butt of a good deal of light wit; the prospect of going to sea in a sieve is charming, says one writer.

Manufactures.

PAPER MAKING MATERIALS.—A society has been formed in France, having for its object the investigation and discovery of vegetable fibres to be used in lieu of rags for the manufacture of paper, and for the organization of mills which should furnish the pulp-stuff to the associated makers. The communications already made on this subject have been referred to the general committee of paper makers as matters for careful inquiry and further proceedings at future meetings. The *esparto grass*, of which some 40,000 tons were exported from abroad for paper making last year, has been found growing along the coast of Cumberland, and local paper makers are carting it to their mills in great quantities, at the merely nominal price of carriage, instead of having to pay five guineas per ton for Spanish.

CHINA GRASS.—The French manufacturers are experimenting largely upon the use of the nettle fibre known under the popular name of China grass. We have been favoured with a sample of fabric made with an equal mixture of 100 kilogrammes of Surat cotton and the same quantity of China grass at Rouen last month. The French papers are freely discussing the report of the Rouen Chamber of Commerce of the 18th ult. on the subject.

GERMAN CARPETS.—Some of the largest carpet manufactories in Germany are established at Hanau, and the carpets made there are said to surpass those made in England, and have a high reputation even in Paris. One of the best known and most extensive carpet manufactories in that town is that belonging to Bernus Leister and Co., especially as regards the finer kinds, which are highly esteemed both for the fastness of the colours and the good taste of the designs. This establishment employs a steam-engine of 20 horse-power, about 160 men, and 100 women. The greater part of the carpets manufactured in Cassel are bought at the Leipzig fairs for the Danubian Principalities. The above-mentioned firm employs 60 or

70 looms for spinning yarns, and altogether about 350 workpeople. Thirty or forty workmen are now employed in carpet weaving in smaller establishments in the city of Camel.

Colonies.

THE BULLER COAL-FIELDS (NEW ZEALAND).—Steps are at length being taken by the Nelson Government, to open out these extensive coal fields. As it is impossible to raise the necessary capital to work the mines in a profitable manner in New Zealand, the authorities are about to send Mr. J. Burnett, who has had considerable experience in coal mining in England, to London, to form a company and raise the necessary capital; this gentleman will be furnished with plans, views, &c., of the district, and will also bring several tons of the coal with him. There can be no doubt as to the richness and extent of these mines.

ELECTRIC TELEGRAPHS (NEW ZEALAND).—The general Government are about to lay down the electric telegraph from Auckland to Dunedin, a distance of about 1,000 miles; although possibly the native war may interfere for some time with its construction in the Northern Island, that portion running through the South Island from Nelson, *via* Picton, Christchurch, &c., to Dunedin, will, it is hoped, be in active operation within a few months, contracts for poles, &c., having been already accepted; whether the rocky deep bed of Cook's Straits will be suitable for a submarine cable remains to be tested by survey and experiment. The distance from land to land is short, being in one place less than 25 miles. It will doubtless be some time before this portion of the work will be undertaken. The Morse instrument will be used.

Publications Issued.

BAROMETRICAL OBSERVATIONS IN THE ANTILLES AND NEIGHBOURING COUNTRIES. By M. C. Sainte Claire Deville. —A remarkable *brochure* on diurnal and annual variation, geographical differences, and the relations between atmospheric pressure and the synodic revolutions of the moon.

NOTES ON A LITTLE KNOWN FUNCTION OF THE PANCREAS—THE DIGESTION OF AZOTIZED FOOD. By M. Corvisart, Physician in Ordinary to the Emperor. Paris. —This work contains the results of the observations of many members of the French faculty, as well as of the author, and has attracted great attention.

Notes.

EXHIBITION OF DEAD POULTRY IN PARIS.—An exhibition of fat poultry is to take place next month, in the Palais de l'Industrie. Intending exhibitors are to apply, before the 1st of December, to the Minister of Commerce. On the first day of the exhibition, the jury will award the prizes in the morning, and the public will be admitted in the afternoon; on the second day, there will be a public exhibition, ending with a sale by auction.

FREE PUBLIC LABORATORY.—The French Government has decided on opening a free laboratory for practical chemistry, the direction being placed in the hands of M. Fremy, Member of the Institute, and Professor. M. Mémier, a manufacturing chemist, who proposed to open a similar establishment, has given up the idea in favour of the government plan, and has contributed the sum of 10,000 francs in aid.

THE TRAGOPAN.—Among the birds just received at the Jardin d'Acclimatation in the Bois de Boulogne, are some

tragopans, a kind of Chinese pheasant, sent by M. Dabry, French consul at Han-Keou. These birds are called Too-chew-kee by the Chinese, a name meaning:—"The bird that vomits flakes of silk." They are brought from the mountains of Sze-Chwen, and also from the Hoopay, Fokin, and Kwang-Tong districts, where they are much esteemed by the inhabitants, both for their plumage and the delicacy of their flesh. Viceroy and rich people always keep some in cages as curiosities. The size of the tragopan does not exceed that of a common hen. Its plumage displays the most varied and brilliant colours. The head is jet-black with a gold-yellow crest; the eyes are large and bordered with blue; the neck is sky-blue, the breast a fiery red; the back and abdomen speckled white on a red ground. During summer it displays the magnificence of its plumage by puffing itself up and strutting about with the pride of a peacock, every now and then uttering a horse caw; then all at once it thrusts out a tongue at least a foot long, of a beautiful blue speckled with fiery spots along the middle, at the same time two charming little blue horns make their appearance on its head. This delightful spectacle lasts about a quarter of an hour, after which the bird withdraws its tongue, lets down its horns, and subsides again into its sober toilette for common wear, uttering an odd sound, as if in mockery of the spectators. This bird, according to Chinese naturalists, is not only one of the wonders of nature on account of its plumage, but it also possesses the most important virtue in the eyes of the Chinese, viz., filial piety, for the young ones take care of their parents when age or illness renders it impossible for them to provide for their own nourishment. This affectionate care has procured this creature the name of Hiao-Ky, or "bird of filial piety." It is also called Py Choo-Ky, or "bird that avoids trees," because it haunts rocks rather than woods. Its flesh is excellent, and the Chinese say it has the property of making a man intelligent. The tragopan is of the pheasant family, and this is the first time it has been seen in France. There is every reason to hope that it will be acclimatised.

Correspondence.

BROKERS AND MIDDLEMEN.—SIR,—Some remarks made by the Vice-Chancellor Sir W. Page Wood, in moving the well-earned thanks of the meeting of the 16th inst. to the Chairman of the Council, for his able address on the opening of the session, deserves, I think, some special notice, as putting in a clear and even a new point of view the real position and duties of the Society of Arts. He said that "this Society filled, with respect to Arts, Manufactures, and Commerce, the position which was occupied in commerce by the 'broker' or 'agent.'" We have so much to learn in this life that it is always desirable, and saves valuable time, if we can thus detect analogies between any two branches of knowledge, or any two systems of organisation which reflect light the one upon the other. This is especially the case if, as in this instance, one branch of the illustration is well known, and does not require to be argued at any length. Many persons then present practically knew the value of the broker, who "ascertained and supplied the wants and needs of different classes of the community." A trader has, perhaps unexpectedly, to buy a particular article. He is a stranger to the market, and goes, therefore, to the broker to purchase. Another trader has the same kind of article to sell, and, going to the same broker, he, the broker, then becoming a "middle man," is thus a convenience to both parties, and a benefit to the community. There is something analogous to this process in the retail shop; the analogy holds yet stronger in the wholesale warehouse, which assembles, under one roof, the productions of various and distant manufactories. So, a Society of Art, of Manufacture, or of Commerce, having relation at once with the inventor and the machine

maker—with the workmen and the employer of workmen—with the actual labourer and the capitalist—with art and the admirers of art—become “middle men” in the noble trade of science, and “brokers” in the exchange and the pursuit of knowledge. I could pursue the analogy further, but, if there be any truth in the analogy, your readers will better pursue it for themselves; and I can only add that, with a Prince for their President, and the heir to the throne in the chair, on the one hand, and their intimate and extensive connection with inventors, designers, manufacturers, and workmen of all classes and ranks on the other hand, it will go hard if they do not conduct their business, as a Society of Arts, Manufacturers, and Commerce, with some degree of credit to themselves and with no small benefit to the community at large.—I am, &c.,

November 21, 1864.

JOHN DILLON.

MEETINGS FOR THE ENSUING WEEK.

- MON. ...**R. Geographical, 8j. 1. Viscount Milton and Dr. Cheadle, “Journey across the Rocky Mountains into British Columbia, by the Yellow Head Pass.” 2. Mr. John Macdonald Stuart, “On his Last Journey of Exploration to Northern Australia, with an Account of the Country about to be Colonised on the Banks of the Adelaide River.” Acturaries, 7. Mr. W. M. Makeham, “Solutions of General Problems in Survivorships.”
- TUES. ...**Civil Engineers, 8. Mr. E. H. Clark, “Description of the Great Grimsby (Royal) Docks, with a detailed account of the enclosed land, entrance locks, dock walls, &c.”
- WED. ...**Society of Arts, 8. Mr. Bridges Adams, “On the Mechanical Conditions of Railway Working to Prevent Destructive Wear and Risk.” Royal, 4. Annual Meeting.
- THURS. ...**Antiquaries, 8. Linnean, 8. 1. Dr. Bastian, “On Nematode Worms.” 2. Dr. Cobbold, “Brief Notice of Results obtained by Experiments with *Entozoa*.” 3. Dr. Baird, “On Tubicolous Annelids, from the Collection in the British Museum.” Chemical, 8.
- FRI.**Philological, 8. Archaeological Inst., 4.
- SAT.**Artists and Amateurs, 7. Annual Meeting.

Patents.

From Commissioners of Patents Journal, November 18th.

GRANTS OF PROVISIONAL PROTECTION.

- Aerated bread—2635—G. T. Bousfield.
- Aeriform bodies, heating, cooling, &c.—2664—D. Laidlaw and J. Robertson.
- Agricultural and traction engines, &c.—2662—J. Craven and S. Fox.
- Animal charcoal, re-burning—2695—J. F. Brinjes.
- Artificial stone—2664—E. J. W. Parnacott.
- Axles—2698—W. E. Gedge.
- Bolts or fastenings—2682—W. Clark.
- Brackets—1975—E. and F. Crook.
- Brushes—2671—J. and P. Goodall.
- Buttons—2703—W. Aston.
- Centrifugal pumps—2735—H. A. Gwynne.
- Chimney pots for prevention of down draft—2775—J. Bell.
- Cisterns, waste pipes of—2725—J. Cutler.
- Clothing for horses, &c.—2705—E. Richardson.
- Cotton-glass—2660—J. Sheldermine.
- Distilling—2749—F. H. Bickes.
- Dyeing and printing, obtaining colouring matters for—2785—J. Dale, H. Caro, and C. A. Martins.
- Electricity, application of as a motive power—2681—L. P. G. Ballet and C. M. P. De Rouvre.
- Electric printing for telegraphic purposes—2687—J. H. Simpson.
- Electric signals for gunnery practice—2483—F. N. Gisborne.
- Fabrics and fibrous materials, drying, &c.—2685—J. L. Norton.
- Filters—2757—J. Slack.
- Fire-arms—2763—G. P. Harding and L. Thomas.
- Fire-arms and projectiles—2649—J. P. Harris.
- Fire-arms, breech-loading—2741—J. Snider.
- Fire-arms, breech-loading—2759—W. E. Newton and E. C. Shepard.
- Fire-arms, breech-loading, and cartridges—2777—S. Rydbeck.
- Fire-places—2694—P. L. Charon.
- Glue and size, manufacture of—2723—H. W. Spencer and J. E. Ball.
- Grain, machinery for cleansing—2755—W. E. Gedge.
- Gunpowder, manufacture of—2594—L. H. G. Ehrhardt.
- Hydraulic engine and pump—2674—G. Rydill.
- Hydrocarbons, distillation of matters capable of yielding—2673—W. Cornack.
- Iron and steel, manufacture of—2738—F. Yates.
- Jacquard apparatus for weaving figured fabrics—2743—D. Ellis and M. Hillas.

- Kneading, measuring, and discharging dough—2694—E. Edwards.
- Lace-making machinery—2676—J. Harshorn and J. Gadsby.
- Lamps for burning magnesium—2690—J. Solomon and A. G. Grant.
- Lamps, preventing extinction of—2700—P. A. Roger.
- Lighting rooms and buildings—2702—I. Schwartz.
- Liquid manure, apparatus for distributing—2693—N. F. Andreassen.
- Marking ink—2511—J. Moller.
- Metallic articles, irregularly formed, machinery for shaping—2679—J. L. Davies.
- Metallic substances, cutting and drilling—2715—C. W. Wardle and R. McIntyre.
- Navigable vessels, constructing—2781—J. Robinson.
- Omnibuses, tell-tales for—2721—W. Newbould.
- Overground telegraph wires, insulating—2636—L. J. Crossley.
- Panels, &c., constructing—2680—A. H. A. Durant & W. H. P. Gore.
- Paper cloth—2311—L. Cooke.
- Paper, manufacture of for preventing falsification of writings—2706—J. Forster and H. Draper.
- Photographic process—2717—T. Fox.
- Pianofortes, &c., stringing and tuning—2697—W. Moody.
- Presses for expressing fluids—2692—J. M. Rowan.
- Railway carriages, applying wheels and axles—2701—W. Rice.
- Railway carriages, warming and cooling—2691—G. Davis.
- Railway carriage signals—2670—W. Dowley.
- Railways, rails for the permanent way of—2677—H. A. and J. E. Jowett, and J. B. Muschamp.
- Railway trains, signalling between passengers and guards on—2712—F. J. Scott.
- Railway wheels and axles, combining—2708—J. Furness and G. Keighley.
- Railways, mechanism for preventing accidents on—2753—G. Simpson.
- Resins and hydrocarbons, manufacturing and refining—2497—J. I. Vaughan.
- Sea-water, conveying to inland places—2783—J. Rao.
- Sewing machines, arrangement of for use in shoemaking—2667—W. Jackson.
- Sextants, &c.—2665—R. A. Brooman.
- Ships' sails, reefing—2570—J. Hart.
- Shovels and spades, affixing the handle to—2449—J. O. Cummiskey.
- Spurs—2737—R. K. and K. T. Bowley.
- Steam-engines—2699—T. Ivory.
- Steam-engines—2711—J. Drury.
- Steel, casting—2714—E. L. S. Benson.
- Sugar manufacture, centrifugal apparatus used in—2678—A. and W. Smith.
- Synphones—2686—G. H. Devereux.
- Syrups, manufacture of—2646—F. Dutrulle.
- Textile fabrics, treatment of—2773—J. H. Johnson.
- Utensils (chamber), fitting and mounting—2669—B. Scalf.
- Vessels and ships, protecting the bottoms of—2672—G. Ager.
- Whip-holder—1846—J. C. White.
- Window-blinds, regulating cords of—2765—R. Montague.
- Woven fabrics, lustring and drying—2739—T. N. Kirkham, V. F. Enson, and H. Brook.
- Yarns, apparatus for wringing, &c.—2661—J. Stobo and W. Pollock.
- Yarns or fabrics, sizing, dressing, &c.—2668—J. and H. Charlton, and J. O. Christian.

INVENTION WITH COMPLETE SPECIFICATION FILED.

Carriages, opening and closing the heads of—2819—C. Martin.

THE Journal of the Society of Arts,

AND OF
THE INSTITUTIONS IN UNION.

111TH SESSION.]

FRIDAY, DECEMBER 2, 1864.

[No. 628. VOL. XIII.]

TABLE OF CONTENTS.

Announcements by the Council:—Ordinary Meetings—Cantor Lectures—Art Workmanship Prizes ... Page	37	North London Working Classes Industrial Exhibition ...	48	Notes:—British Museum—Lighting Moscow with Gas—New Laboratory for Dr. Hofmann, at Berlin—Fire Arms ...	50
Proceedings of the Society:—Third Ordinary Meeting—On the Mechanical Conditions of Railway Working to Prevent Destructive Wear and Risk ...	37	West London Working Classes Industrial Exhibition ...	49	Correspondence:—Mr. Fairbairn's Paper—Fire-proof Construction—Ships and Guns ...	51
Discussion ...	48	Manufactures:—Textile Manufactures—Lenoir's Gas Engine ...	49	Meetings for the Ensuing Week ...	52
Proceedings of Institutions:—Worcestershire Union of Educational Institutes ...	48	Commerce:—External Trade of the Country—Banking in Frankfurt—Grapes from the United States ...	49	Patents ...	52
		Obituary:—M.A. Lefevre—David Roberts ...	50	Registered Designs ...	52

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

DEC. 7.—"On the Construction, Retardation, Safety, and Police of Railway Trains." By W. BRIDGES ADAMS, Esq.

DEC. 14.—"On the Recent Progress and Present State of Industry in Ireland; and the Dublin International Exhibition of 1865." By Sir ROBERT KANE, F.R.S. On this occasion Lord DUFFERIN will preside.

DEC. 21.—The Articles sent in Competition for the Art-Workmanship Prizes will be Exhibited, and a Report in connection therewith will be read.

CANTOR LECTURES.

There will be three Courses of "Cantor" Lectures on the following subjects during the ensuing Session:—

"On the Reproduction of Natural Forms by Art and Manufacture." By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

"On the Application of Geology to the Arts and Manufactures." By Professor D. T. ANSTED, M.A., F.R.S.

"On the Application of Chemistry to the Arts." By Dr. F. CRACE CALVERT, F.R.S.

The following is a syllabus of Mr. Hawkins's course, with the dates of delivery:—

DEC. 12TH.—LECTURE I.—INTRODUCTORY:—On the nature and probable influence of museums of natural history and art collections, and their effect on the public mind and taste. (Illustrated.)

DEC. 19.—LECTURE II.—Demonstrations of the unity of plan in the external forms of animals, the just appreciation of which facilitates the work of the artistic producer, and adds to the enjoyment of the intelligent possessor of works of art.

JAN. 16TH, 1865.—LECTURE III.—On the varieties of artistic treatment of the forms of animal and vegetable life—pictorial representation; conventional ornamental, allegorical, and symbolic combinations of animal forms.

JAN. 23RD.—LECTURE IV.—On the fitness of designs, and their adaptation to the conditions of the materials in which they are to be produced. (Demonstrated by metal-work processes, sand-moulding, casting, and chasing).

JAN. 30TH.—LECTURE V.—On Ceramic Manufactures, with the influence of the material on the design and its successful production—modern Terra-Cotta, Della Robbia ware, Majolica, and Faïence.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture.

ART-WORKMANSHIP PRIZES.

Articles (ninety-six in number) sent in competition for the Art-Workmanship Prizes, have been received from seventy-three competitors, and will be arranged for exhibition in the Society's rooms on and after Wednesday, the 21st instant.

Proceedings of the Society.

THIRD ORDINARY MEETING.

Wednesday, November 30th, 1864; Captain Douglas Galton, R.E., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Barnes, Joseph, 5, St. Thomas'-street, Borough, S.E.

Batson, John, 42, Brewer-street, Golden-square, W.

Dear, Alfred, Pavilion, Belgravia, S.W.

Dear, Arthur, Pavilion, Belgravia, S.W.

Forristall, Michael, The Hermitage, Forrest-hill, S.E.

Grundy, John, The Middle Temple, E.C.

Hall, J., 29, Warwick-square, S.W.

Huth, Edward, Oakfield Lodge, Huddersfield.

Lane, William James, 5, Studley-villas, Studley-road, Clapham, S.

Lord, James, St. John's Lodge, Wandsworth-common, S.W.

Monteith, James, 38, Duke-street, St. James's, S.W.

Moss, William H., 19, Parliament-street, Hull.
 Rochussen, Theodore Anthony, 9, Friday-street, E.C.
 Saunders, Edwin, 13a, George-street, Hanover-square, W.
 Schweizer, J. J., 28, Poole street, New North-road, N.
 Scott, Rev. C. B., 19, Dean's-yard, Westminster, S.W.
 Turner, Henry, St. Joseph's road, Higher Tranmere, Birkenhead.
 Twentymau, William Holme, Manor-hill, St. John's-wood, N.W.
 Vaudrey, Henry, 10, Norland-square, Notting-hill, W.
 Walker, G. H., Rugby.

The following candidates were ballotted for and duly elected members of the Society:—

Altschul, Dr. D. H., 9, Old Bond-street, W.
 Bickerstaff, William Martin, 13, Highbury-terrace, N.
 Bussell, Charles, 26, Soho-square, W.
 Clauson, Charles A. R. (Messrs. Rogers, Bros., and Co.), Naples.
 Clutton, Robert, Hartswood, Reigate.
 Craven, Joseph, Dole Mill, Thornton, near Bradford, Yorks.
 Crowther, Wm., Chemical Works, Gomersal, near Leeds.
 Darkin, Charles James, 21, Victoria-terrace, Finchley-road, N.W.
 Dyer, George, 90, Regent-street, W.
 Eskell, Abraham, 8, Grosvenor-street, W.
 Evans, John James, Rose-bank, Rock-park, Birkenhead.
 Field, John Lyon, Upper Marsh, Lambeth, S.
 Ford, Herbert, 8, Pier-road, Erith, S.E.; and 1, Charlotte-row, Mansion-house, E.C.
 Frean, G. H., Mill-street, Dockhead, S.E.
 Gilbert, Arthur, 12, Claverton-street, Pimlico, S.W.
 Green, German, 7, Helmet-row, Saint Luke's, E.C.
 Hannah, Robert, 2, Alfred-place West, Brompton, S.W.
 Hart, John Matthias, 76, Cheapside, E.C.
 Haysman, Jas., F.R.G.S., Burdett House, Burdett-rd., E.
 Hollow, Richard Welch, York.
 Hudswell, W. S., New Railway Foundry, Leeds.
 Huggon, William, 30, Park-row, Leeds.
 Lainsou, Henry, Heath-house, Reigate.
 Leycester, George Percival, 6, Oak Hill, Hampstead-road, N.W.
 Locket, George, Acton-house, Roselyn-park, Hampstead, N.W.
 Mather, William, Chester-road, Manchester.
 Morres, Edward, 43, Parliament-street, S.W.
 Nosotti, Charles, 398, Oxford-street, W.
 Oertling, Ludwig (Ladd and Oertling), 27, Moorgate-st., E.C.
 Oram, John White, 7, Bank-buildings, E.C.
 Payne, James Bertrand, 44, Dover-street, W.
 Page, Nathaniel, Stag Brewery, Pimlico, S.W.
 Pankhurst, R. M., LL.D., South King-street, Manchester.
 Robinson, James Edward, Pontefract.
 Smith, Joseph, 3, Percy-villas, Wells-st., Hackney, N.E.
 Snooke, William, 6, Duke-street, London Bridge, S.E.
 Talbot, Robert, Strand-on-Green, Chiswick, W.
 Taylor, John, 45, Connaught-terrace, W.
 Tucker, Silas, 54, Canonbury-park south, N., and 234, High Holborn, W.C.
 Turnbull, Thomas, jun., Whitewell Dockyard, Whitby.
 Venables, William Vernon, 6, Queen-street-place, E.C., and 20, Canonbury-villas, N.
 Wagstaff, John Henry, 9, Sheldon-street, Bishop's-road, Paddington, W.
 Walker, W., jun., J.P., Red Hall, Shadwell, near Leeds.
 Watkins, Major-General, B3, Albany, W.
 Watson, Edward Façon, 201, Piccadilly, W.
 Wateon, Thomas, 19, Highbury-crescent, N.
 Wentworth, J. W. T. Vernon, Wentworth Castle, Barnsley.
 Whiteside, R. B., 49, Lime-street, E.C.
 Whitford, Edward Edmondson, 55, Lansdowne-road, Kensington-park, W.
 Willing, James, 366, Gray's-inn-road, W.C., and South Lodge, Ham, S.W.

Wilson, Captain J. H., 35, Pembridge-villas, Bayswater, W.
 Wilson, George, Nunthorpe Hall, York.
 Wilson, Thomas, 20, Gloucester-square, Hyde-park, W.
 Woodthorpe, Edmund, 28A, Basinghall-street, E.C.
 Wrentmore, Francis, 250, Regent-street, W.
 Yallop, Thomas, 39, Norfolk-square, Hyde-park, W.

AND AS HONORARY CORRESPONDING MEMBERS.

Bonghi, Cavaliere Diego, 38, Vico S. Guiseppe de Midi, Naples.
 Knight, J. G., Melbourne, Victoria.

The Paper read was—

ON THE MECHANICAL CONDITIONS OF RAILWAY WORKING TO PREVENT DESTRUCTIVE WEAR AND RISK.

By W. BRIDGES ADAMS.

This is a subject not of mere local or of class interest. In days gone by, when a man was by the mass of Cockneys esteemed a traveller if he had been to Gravesend and back, it would have interested but a very few to discourse on the means of transit, but in the present day, all men, women, and children have become locomotists, getting back to a state of nature, like the birds and wild animals, and no longer confined to the spot on which they are born and bred. And a very good thing it is for themselves and general humanity, for they thereby become educated, not in the sense of book learning, but in the sense of knowledge of men and things, expanding their thinking faculties with the more healthy growth of their bodies. We increase thereby the number of men and women, instead of mere human animals, and we increase also national power, which is not to be measured by animal units, but by the mass of intelligence, health, and physical strength—in short vitality. It is better to soar like birds than to burrow like rats; and though we cannot soar above the earth, with guiding power like birds, we contrive to skim along the surface though not quite so fast, and do not yet see our ultimate limit to speed accompanied by safety. We are fast becoming a nation of mechanicians, and each man's strength is as the strength of ten, as fast as he acquires a sound body for a sound mind to dwell in. The subject is possibly a dry one in its details, but out of these dry facts must come the growth of progress, and this must be the writer's apology for dwelling on them, though in as succinct a mode as language will permit. In criticising any subject it is but natural that the critic should devise plans for amending that which he deems wrong, and in so doing the writer would deprecate any appearance of egotism in dealing with his own plans.

In vehicular transport the contact between the vehicle and the road it moves on may be of three kinds, sliding or sledging, rolling, and a compound movement, partly sledging and partly rolling. The sliding movement may be converted into rolling by the application of water, oil, or unguents, the particles of which form rolling bodies between the vehicle and the road, as with the ship on water, or with the wine sledges used in Madeira, where the driver sluices the road beneath the sledge runners, or with the winter sledges of cold climates, where frozen surfaces supply rolling particles. If actual contact between the moving vehicle and the road take place without the intervention of rollers or lubricants, destruction must ensue by abrasion.

Where no means exist of supplying lubricants to the road surface, the next process to ease the sledge is to place rollers under it. If the rollers be true cylinders, and are not fixed to the sledge, and the movement be in a straight line, there will be absolute movement without friction. If the rollers be fixed to the sledge, by axles passing through them and bearing the load, the friction will be transferred to the surface of the axle from the surface of the road, and will be greatly reduced if the oil or unguent forms an efficient lubricant. If the roller

be on the road through its length, and be a true cylinder, it will move forward in a straight line. If it be of a conical form it will move in a curved line corresponding to the cone. But if two coned rollers be fixed to the sledge with their axes parallel, the movement will be partly sliding and partly rolling, with great friction in a straight line. If the two coned rollers be not parallel, but are arranged with their axes in converging lines corresponding to the cones, the machine will move in a circle, the centre of which will be the point where the converging lines intersect each other.

The ancient Greek and Roman cars were mounted on wheels, i.e., a pair of wheels connected by a fixed axle running between thole-pins, such as up to the present day are in the wine-cart of Portugal and parts of Spain, which are unfitted to turn corners, and make so fearful a squeaking when running out of a straight line as to give rise to the jest that they are so ordered to give warning to the custom-house officer in case of smuggling. Double-roller cars also existed, with fixed parallel axes, and this faulty mechanism was probably one cause why the old Roman roads were made in straight lines, as it was easier for such cars to run up hill than to follow curves. Even supposing the case of four-wheeled cars with two wheels running independently on their axes, these cars would only run in straight lines as long as their axes were rigidly parallel; and in England it was only during the reign of Queen Elizabeth that what were called "trailing carriages" first existed, i.e., with a mechanism that permitted the axes to depart from their fixed parallelism to pass round curves.

When railways, as distinguished from tramways, were first commenced, the faulty mechanism of the early classic cars was resorted to as a cheap structure—cheap in first cost. Wheels proper were ignored—i.e., wheels running independently on their axes—and rollers were used, i.e., wheels fixed to a shaft or axle which revolved with them in thole-pins, or what are now called horn-plates. And, whether two axes or three or more were used, they were always rigidly parallel. And this is the common practice in England to this day.

What are called tramways are formed of flat plates of iron, with rising edges to keep the wheels in track. Ordinary wheels, revolving independently on their axes, revolved on them. Their mechanical disadvantage was that dust and dirt accumulated on the horizontal plates, and the wheels rubbed hard against the rising edges as against kerbstones, and caused much friction. Opinions are divided as to the origin of the term tramway, whether derived from an originator named Outram, or from the word "trammel," to curb or guide. The term "plate-layers" on railways, is evidently derived from the original tram-plates. On railways proper, what is called the edge rail is used, in which the increased depth gives greatly increased strength to support the load, and at the same time dust and dirt have little chance of remaining on the rails. But to keep the wheels on, the rising ridge or kerb of the tramway is transferred to the wheel, in the form of a flange. It is clear that vehicles with fixed wheels and parallel axes are only adapted to move in straight lines. If the axes were converging, the vehicles would only move in curved lines. But there is another common condition, a result of faulty workmanship—parallel axes not at right angles to the line of traction; in this case the machine becomes a sledge under all conditions, with the wheel flanges constantly grinding against the rails.

With a view to compensate, on curved lines of rails, for the different lengths of pathway on the two rails, it has been a practice to make the wheel peripheries conical instead of cylindrical; i.e., each pair of wheels fixed on the axle being practically a garden roller, with the central portion removed, are made at each end a frustrum of a cone, with the smallest diameters outside. Were the roller solid, i.e. were the coned lines prolonged till they met in the centre, the roller, if balanced, might run in a straight line, or it might run in a

curved line to right or left, if bearing on either cone, the curve being regulated by the angle of the cone. This would be the case with a single roller. But it is a fallacy to suppose that two or more rollers fixed in a frame, with their axes permanently parallel, would follow the same conditions, even though sufficient end-play were allowed between the flanges and the rails to make the differing diameters across the breadth of the tires available to compensate for the differing lengths of the rails. The movement in a straight line might be free rolling at low speed, provided the cones had sufficient lateral movement or end-play, but on curves it would only be sliding or sledging. But if the frame were so arranged that the axes were permanently out of parallel by reason of careless workmanship, the machine would be a constant sledge both on straight and curved lines. So also if the axes were perfectly parallel, with the wheels in the same plane, but were not placed at a right angle with the line of traction, the result would be constant sliding friction.

In any of these four conditions—whether a truly constructed frame, with parallel axes, or badly constructed with axes out of parallel, or badly constructed with parallel axes and wheels out of plane, or not at a right angle with the traction rod, though the first may roll at intervals under a favourable condition, the three latter must always slide, and the resistance to traction will be in proportion to the roughness of the rails and the load on them. With a light vehicle, little loaded, smooth wheels and polished tires and rails, and especially if they were lubricated on the surface, the resistance might be very small. Nay, a sledge might even be better than a wheeled vehicle, if only the condition of a lubricant could be retained. But a lubricant on the rail is inadmissible, first, because it would cause dirt to adhere to the rail, and secondly, it would defeat the condition of adhesion essential to the traction by the locomotive engine. The engine needs the greatest possible amount of adhesion, corresponding to the steam power. The vehicles should be so constructed as to minimize the amount of resistance. But as at present constructed, the vehicles on a railway are in principle a reproduction of the old Roman cars on two rollers, with such variation as a better or worse condition of workmanship or lubricant may induce, and the change from a common road to a railroad.

Axle friction, under the best conditions, is commonly estimated at about four pounds per ton of load, but this is usually doubled by a condition that under the best treatment ought scarcely to exist, viz., "rolling friction" i.e. the friction of the tires on the rail, and thus at a moderate speed on the level, eight pounds per ton is estimated as train resistance. But this, it is well known, is very far short of the real resistance in practice, which by quick curves and bad structure may be quadrupled and quintupled, varying with the speed of movement.

A river running with a slow movement may pass along a winding channel without disturbing its banks; but the same river, with its speed increased by sudden influx of water, seeks to make a straight course, and cuts away its banks, or *rives* them, in a mode corresponding to its etymology. Even so, a railway train at high speed becomes a *river* of the rails, at an increased cost of coke converted into steam; and, like the river water, it produces debris, not in the form of gravel, but of black iron powder, as anyone may verify by rubbing his finger along the rails after the passage of a train. This is frictional destruction, increased or diminished, in proportion to the load on each wheel.

But there is yet another element of destruction—percussion or blows, which take place between wheel and rail, friction and percussion being the only sources of mechanical destruction on railways—the others being chemical. It is quite clear that were a train to stand still on a railway, and never move, it might rust and rot, but it would not wear out, and though the proverb is a sound one "better rub than rust," it is still better to do neither. The movement of the train begins the great destruction,

and it is want of compensation for irregularities—a condition never disregarded by nature—that causes the destruction. The wheels, when running on unequal paths, induce great torsion of the axles by friction on the rails. At bad joints or uneven surfaces the wheels jump from the rails, and they then recover their normal position, by the axle as it were unwinding itself, like a discharged spring, and striking a violent blow on the rail. Sometimes the wheels, with the axles in a state of torsion, drag along for a considerable distance, heavily loaded, and this is a fruitful source of axle breakage, as well as of rail destruction. Again the flanges strike against the rails from side to side, and a constant succession of blows and vibrations is induced throughout the whole of the train. And with long vehicles, on sharp curves, there is a constant tendency to grind the flanges and burst out the rails. The rapid wear of wheel tires and rails yields ample evidence of this, and the probability is that at high speed the movement is as much sliding as rolling—side as well as forward sliding. But for the partially polished surfaces of both wheels and tires facilitating slip, at the loss of adhesion on the driving wheels, it is probable that the destruction would be much more rapid.

Are there proofs needed of all this? Time was that rails of 60 lbs. per yard, and Staffordshire tires too tough in texture to break, were capable of considerable duration. They have gone by, and rails, after various experiments in making them harder in iron, have grown to 84 and 90 lbs. per yard, and now with Bessemer steel for metal; and tires, after running through the phases of Park-gate, Low Moor, and Leeds, and various plans for steeling their surfaces, have now culminated in Krupp's solid steel.

It is many years since the writer became aware of the importance of elastic action, even on wood wheels used on highways and paved streets, to induce durability, and facilitate traction, when high speeds were needed. In the structure of the ordinary wood wheel the strength resides in the tire, which keeps the weak frame together. Originally, wheels were made vertical, *i.e.*, with the spokes all in a plane, and the width of base was determined by the ruts or hollows which pervaded all roads, giving a kind of fixed gauge, much as rails do now. The bodies were placed between the upper part of the wheels; and when it was needed to widen the bodies, the wheels were made in the form of a cone, or what is called "dished," the axle arms being pitched downwards to keep the lower spokes vertical, with an idea of strength, while the upper spokes inclined outwards with a considerable angle. The fellys and tire were made conical, to preserve a flat tread on the ground. It is evident that as these wheels revolved, they were constantly grinding the road, the outer side of broad wheels being considerably less in diameter than the inner, while the vertical spokes were continually driving into the nave and loosening the framing.

After trying some experiments with wheels in which hoops of elastic steel were used to connect the periphery with the nave, instead of spokes, the writer had some made with the section of the wood spokes reversed. The ordinary mode is to make the spokes deepest from back to front, but in the improved samples they were made broad in the plane of the wheel, and thin from front to back. As this was a bad form to fasten in the ordinary nave, it was dispensed with, and a pair of disc plates was substituted, between which the spokes were mitred together and bolted. One felly was used to each spoke, instead of the ordinary practice of one felly to two spokes, and when cylindrical tires—not conical—were shrunk on, the spokes curved from back to front, and the wheel, instead of being a rigid cone, or dish, became an elastic dome, each pair of opposite spokes radiating from the centre, representing the form of an archer's bow. The fastening of the tires was through the joints of the fellys. When applied to a straight axle, with the arms not pitched downwards, the load was carried, not on a rigid vertical, but on a bent inclined spoke, and the re-

sult was that the load was not only carried more easily, but the wheels were, for their scantling, the most durable ever constructed.

In the early railway wheels the principle obtained of neglecting the structure of the frame, and making it depend for strength on the shrinking of the tire, just as wood wheels were made. One result of this was the flattening of the tire between the spokes, and a tire of unequal thickness, when turned in the lathe to make the external periphery a true circle, and a consequent rapid destruction in wear. This applied to the wheels with the wrought-iron spokes. The truest formed wheels were those of cast-iron with a wrought tire. They might break if of careless moulding, but they would not otherwise alter their form, and the tires could be all of equal thickness. But upon rigid cast-iron wheels the tires became exposed to very rapid destruction as the loads increased.

The writer had early turned his attention to the importance of wood wheels for railways, and as far back as the year 1838 caused some to be constructed with two rows of fellys, break-joint between the tire, and a cast centre. They worked well, and the writer has been informed that they still exist. The difference between these wheels and the modern wood wheels is that they had the elastic side grain on the tread, whereas the modern wheels have end grain. The reason for substituting the latter less perfect method probably was the difficulty of ensuring dry timber on a large scale, and wood shrinks scarcely at all endwise, so that the shrinkage involves less evil.

Wood wheels on railways are, as now made, solid discs, and therefore the frame preserves its circular form without being excessively rigid. Iron wheels have also been made in the disc form, both in cast and wrought iron; but, then, extreme rigidity rendered the destruction of the tires a very rapid process;—the tire was between two anvils—the frame of the wheel, and the rail supported on chairs of cast iron.

To prevent this destruction the writer early devised a wheel in which the spokes were all springs, but that did not answer, because the bending of the spokes prevented the wheel from running true. The next plan was to apply a hoop of elastic steel between the tire and the periphery of the wheel, with a hollow below the steel. The wheel was retained in the tire by a rising rib in front, solid with the tire, and by a lower rib behind, sprung into a groove of the tire. Models are on the table and a section on the wall.

The plan was satisfactory in theory, but how to put it in practice was another matter. A railway was needed, and railways are not to be found in a private field or park; they are the highroads of the public, and in charge of officers whose first care is to take no risk by an unknown plan; for if an accident happens through a known plan in common use, however faulty in its mechanical philosophy, a jury will acquit the manager of all blame. But if the accident happens with a novel plan, however theoretically right it may be, the jury will probably condemn it as new-fangled, and saddle the manager or engineer with the blame; and thus there is a natural indisposition in engineers to step beyond their tether into the unknown, and they can hardly be blamed for their caution.

So the writer went forth on his propaganda to expound an unknown quantity, but few would even listen to him, and none would believe; but strong in faith he persevered, and at length found an engineer with a logical mind, in the locomotive superintendent of the North London Railway, Mr. William Adams. The writer demonstrated his principle, and Mr. Adams was unable to disprove it logically, whereon the writer remarked, "If you cannot demonstrate it to be wrong, and I demonstrate it to be right, and that the result if successful must be very advantageous, you are bound to try it." He agreed to this, and said "I will try it, though doubting greatly. What wheels will you apply it to?" "Those most destructive to tires."

So a set of wrought iron disc wheels were selected, and Staffordshire tires were applied to them on hoop springs, and they were placed under a heavy carriage. At the same time a set of ordinary spoke wheels, with a set of Low Moor tires fixed in the rigid mode, were applied to a similar carriage. The Low Moor tires required turning up to restore their surface after running less than 50,000 miles. The Staffordshire tires on springs ran 106,000 miles without turning up, and with no alteration of form, and were then taken off to exhibit, and may still be seen in the same condition.

There is no mystery in this. The Low Moor tires were exposed to severe wear. First, because on curved lines they were necessarily forced to slide on the rails, both forward and laterally. Secondly, because they were rigidly fixed, and possessed no elastic yielding to slide blows. Thirdly, because on curved lines there was a constant torsion of the axles causing incessant jumping. Fourthly, because the tires had no power of lateral movement to suit the varying inequalities of the rails. In short, there was no compensation for irregular movement, and the result was a constant grinding of the flanges and tracks.

With the spring tires, on the contrary, there is universal compensation. First, there is no tendency to blows, because the elastic cushion preserves constant contact between tire and rail. Secondly, there is no torsion of the axle or slipping of the tires on the rail because the wheel can, on curved lines, slip in the tire on the smooth surface of the spring without damage, thus equalising the pathway. Thirdly, the tire can rock laterally on the wheel to adjust itself to the bearing on the rail surface, which any one may observe to be constantly varying, sometimes the middle of the rail being most prominent, sometime the inside edge, and sometimes the outside. No other class of wheel can supply these various compensations.

Important as these wheels are for vehicles which are simply drawn, in order to remove resistance, they are still more important for engines with the load greatly increased, and especially for driving wheels—more especially for engines with four coupled drivers. It is obvious that if two wheels of equal diameters be fixed on the same crank shaft they must grind and drag on curved lines, and the torsion thence ensuing is the main cause of the breakage of crank axles, which it is difficult to make strong enough for their work, the axle being in reality a very long axle, as would be readily apparent were it stretched to a straight line—between eight and nine feet long on the narrow gauge. When four wheels are coupled, the diameters very rapidly alter by irregular movement, and the adhesion may actually become disadvantageous, marring the engine by friction, like a brake. It is clear therefore that the power of slipping the wheel within the tire to compensate for curves and irregularities becomes a question of the greatest importance, both as to facilitating haulage and preventing the wear of tires.

It has been at times assumed that the slip of the tire on a wheel must defeat the purpose of haulage. But when it is remembered that the bearing of the wheel is over half the diameter by downward pressure, and that with a heavily-loaded wheel a slight flattening of the tire takes place, it is obvious enough that slip will only take place by excessive friction on the rail; this is the true theory, but, for the satisfaction of those who only believe in practical results, it may be stated that the experiment has been tried repeatedly, and it has been found that when the tires were so loose on the springs as to be turned round by hand with the wheel lifted, the haulage was in no way affected. On a London line, of sharp curves, where the leading tires of ordinary engines with parallel axles had their flanges constantly ground off in two months' wear, a boggy-engine was set to work with a turning centre to radiate the leading axle to the curves. At the same time a similar sized engine, but with parallel axles, was applied with spring tires to the leading wheels. The result was that in both cases the leading flanges were

saved from damage, and ran three times the ordinary distance. The yield of the springs had an effect similar to that of the play of the axle to right and left in the boggy, when truly centred, for if not truly centred the flanges wore unequally.

These spring tires were adopted on the engines of the St. Helen's line, by Mr. James Cross, the engineer. That line is an incessant continuation of sharp curves and gradients, some of the latter 1 in 35, and some of the former two chains radius. The spring tires were first applied to a six-wheeled engine, all coupled drivers of 4 ft. diameter. They were all of Staffordshire iron. At the same time another engine of less weight, also on six wheels, but of 4 ft. 6 in. in diameter, and only four coupled, was fitted with tires of Krupp's steel. After running 41,000 miles, Krupp's tires were so deeply worn as to need turning up, while the Staffordshire iron tires ran 65,000 miles, and then only required the flanges to be reduced which had been deeper at the outset, the tread of the tire remaining in good shape. Taking into consideration the difference of diameter, the distance run by the Staffordshire iron was as 72,000 against Krupp's steel 41,000. In practice, Krupp's tires were found to slip on the rails even in dry weather, but the Staffordshire iron was scarcely ever known to slip, though working steeper gradients and sharper curves.

Another set of experiments was tried with two fellow engines, one of them fitted with spring tires, the other with rigid tires, up a gradient of one in 80, during a whole day, by the same driver. The result was, that the rigid tires constantly drew up thirteen loaded coal wagons, and the spring tires fifteen.

The result of this elastic principle having been so unmistakably advantageous in wheels, the writer began to consider whether the same principle might not be practically applicable to rails also. It is clear that the destruction of rails arises from blows between the wheel tires and the rails, increased in destructive effect in proportion to the load, and therefore it is, that it is now proposed by some railway companies to substitute steel for iron in rails as well as tires.

On the North London Railway the rails are 82 lbs. per yard, and their average duration on the main line does not exceed four years, if so much, the traffic on each pair of rails being upwards of 120 trains per diem of goods, coal, and passengers. The great wear is not owing to wear of attrition, but to crushing, disintegration of the laminae. The rails are double-headed, and worn out on both tables before they are taken out. The sleepers are three feet apart, and the rails are fixed in cast iron chairs with wooden keys, the joints being fished with long fishes and four bolts.

Iron rails are in their manufacture practically "scrap iron." They are formed of bars of various sections piled together and heated, and then rolled out. In the act of heating, the oxygen of the atmosphere gets access to their inner surfaces, and scale is formed. This scale does not roll out, but rolls in, keeping up a constant separation of fibres like the grain of wood. With a certain intensity of blow on the line, the chairs and sleepers serving as anvils, the fibres are crushed apart, and the utility of the rails is destroyed.

Steel rails are not formed of separate masses welded together, but each of a single ingot rolled out without flaw or imperfect junction. They are homogeneous, which

the iron is not, and therefore do not disintegrate with the same amount of blow which disintegrates the iron. But to be safe, the steel rail requires to be not only homogeneous in metal, but in the temper of the metal also. If a steel rail be taken hot out of the rolls and thrown on a cold iron or stone floor, it may become partially chilled—hard and soft—and in this condition it is apt to break, for which reason it is always recommended to keep the steel rails as soft as possible, to prevent risk, in fact to reduce them to the condition of iron. But the better plan would be to use spring steel, and harden and temper it.

There is a notion prevailing that permanent way on cross sleepers is elastic by virtue of its discontinuous bearing. But it is obvious that if there be any yield of the rails between the supports, there is none at the chairs themselves. If the rail be loose in the chair, which it commonly is, and if the sleepers be loose in the concreted ballast, which they are commonly, the looseness only serves to give momentum to the blows of the wheels, so that the rail drives into the chair, the chair drives into the sleeper, and the sleeper drives into the ballast, while the fish joint bends at the weakest point.

On a portion of the main line of the North London,

the rails and chairs being taken up, longitudinal timbers, four inches deep by eleven inches wide, were spiked down to the sleepers. On these longitudinals, midway between the sleepers, were placed cast-iron brackets in which the rails were fixed, suspended by the upper table, and not resting on the lower table, as in chairs, the bottoms of the rails being 1½-inch above the longitudinal timber, so as not to touch it. The joints were fastened as usual. The cross sleepers were packed hard and tight on solid ballast. The longitudinal timbers were not packed, the result being that the rails were continuously supported on an elastic base. With the traffic of the trains the mechanical action was, that no wheel pressed directly on a single sleeper with a hard blow, but that the weight on each wheel was distributed over two or more sleepers, and that through an elastic medium. Practically, after nearly three years' wear, none of these rails have been found to disintegrate, but are as perfect as when first laid down, except where connected rigidly to the ordinary line, and there the ends of the rails are split; and the elastic action is not merely vertical, but horizontal also, by a slight twist of the longitudinal timbers preventing side blows from the flanges of the wheels.

It was also found that the sleepers remained quite undisturbed in the ballast, owing to the distribution of the weight, and that they really became *sleepers*, instead of dancing up and down. Moreover, the provision for elastic action dispensed with the practice occasionally resorted to of digging up the ballast below the sleepers to soften it, and prevent the extreme rigidity. It is getting to be a known fact that constant traffic and the use of heavier engines and vehicles is gradually solidifying the whole of the railway lines, so that the destruction of the plant, both fixed and rolling, is on the increase. A superintendent of a long line running on hard ground informed the writer that he contemplated re-spacing the whole of his sleepers in order to use the softer intervals. An illustration of this great evil may be found in the fact that in the winter time, when all the ground becomes hard with frost, the destruction of wheel tires and rails by breakage, is greatly on the increase.

After the successful result of the first experiment on elastic lines, the superintendent of permanent way, Mr. Matthews, laid down a second portion, in which the cross-sleepers are six feet apart, or double the ordinary distance, the supports of the rails on the longitudinals being three feet apart. The same result was obtained in preserving the sleepers steady in the ballast, though the elastic yielding was greatly increased, being quite perceptible under the rolling trains.

Ballast in England and elsewhere has become a kind of stereotyped custom on railways, though there are districts, as Egypt,—the Southern States of America—where a driver “guesses he never run on ballast but only on mud roads”—the Pampas of Buenos Ayres, the Llanos of Venezuela, and elsewhere, where no ballast can be had, and so it is dispensed with. But the theory of ballast has hardly been considered. It was originally used on non-porous soils, as a kind of easy drainage for surface water, and in some places tolerably cheap. And it does not yield like clay. But it very soon ceases to be porous under the sleeper, and becomes a kind of conglomerate, or concrete, each sleeper pit holding water like a pond. But inasmuch as it has been practically demon-

strated that with a provision for elasticity the sleepers may advantageously be rigid fixtures, there seems to be no reason why the whole surface of a railway should be covered with eighteen inches of gravel or broken stone, varying in price from 1s. to 2s. 6d. per cubic yard. The object should be rather to cover it with non-porous material, so as to keep out the surface water, the same principle on which we pave the footways of our streets; and there is no doubt that it would be cheaper in many cases to use stone flags or cast-iron for sleepers, rigidly fixed and overlaid with elastic longitudinals, so as to dispense with ballast, even in first cost, saying nothing of the saving in maintenance. As regards such lines as are constructed on brick arches, the elastic system would prevent the vibration which so commonly disintegrates them, and, by ramming down the ballast, forces out the parapets; and it would be better to cover the surface with non-porous material, such as paving stones, and get rid of mud and dust altogether. The action of this novel system depends upon the elasticity of the longitudinal timber, but inasmuch as there are circumstances in which timber is inadmissible, such as very hot climates, or climates of great heat and moisture combined, or alternating, the writer was led to consider whether it might not be practicable to obtain the elasticity by the agency of metal. This can be done in two methods, substituting a broad T iron for the longitudinal timber, or by applying springs of tempered steel beneath the seats of the rails, which in that case cannot be suspended by the upper table, but must rest below the vertical web, being supported between the bracket sides with provision for the small amount of movement required. Two models of cast sleepers are on the table, with elastic steel bases. The cost of them will not exceed ordinary iron way, as great weight of metal is saved.

It is desirable that the rails should be of such depth as not to deflect beneath the wheels, and also that they should not deflect laterally, for which reason the tables should be of ample width. It is also important that the rails should be so joined together as to form non-deflecting bars at the joints, though with provision for expansion and contraction. In examining the ordinary fishes it will

is perceived that the original principles of the writer's invention have not been carried into effect. These fishes, as ordinarily used, are parallel bars, about eighteen inches in length, and with four bolts to attach them to the rails. As the total depth of the fish is only between two-and-a-half to three inches, it is obvious that a pair of three inch bars cannot possibly be equivalent in strength to a rail five inches in depth, and provided with two broad tables. In order to compensate for this defect in some measure, the fishes are made as thick as possible, approaching an inch, making them very rigid. They are wedge-formed between the rail-tables, but at an obtuse angle, not an angle of repose, and they depend wholly on the bolts to keep them in position under the action of the trains, and the slightest movement of the rail loosens them. For this reason the bolts are made as large as possible. The large hole weakens the fishes, and it is necessary to drill the holes, as punching distorts a narrow thick bar. Moreover, as the fish is as thick at the ends as at the centre, the result is a blow from the wheel at the end, where it is too strong, and a second blow at the joint where it is too weak, and a gradual dent of the fish-end into the rail, and another dent of the rail end into the fish, and when these dents begin to form, the process of destruction is certain; rust is formed, rubbed off, and begins again, and the noise and jolt is rendered very perceptible to the passengers before the cause is detected by the eye, except when a train is passing, when the deflection is very perceptible.

To remedy this evil, the writer has devised a true form of fish. It is tapered from the ends towards the middle, where it is the full depth of the rail on the outside fish, and on the inner the full depth of the rail, less the upper table to make room for the wheel flanges. Angular ribs are rolled on the inside of the fishes, to fit accurately against the rail tables, and the fishes are arched laterally. The metal being thin, except at the ribs, they are easily punched without distortion, and when the bolts are screwed tight, the arches of the fishes flatten and press the ribs against the rail tables firmly. The bolts thus acting on elastic surfaces, the nuts remain tight, and the joint is elastically firm. The models of the elastic way, both in timber and iron, with steel springs, as well as the improved fish joint, are on the table.

The writer has dwelt upon this subject the more earnestly because on any new plan connected with a railway, a protracted experiment is needed for verification, and this protracted experiment of elastic railway has been made, and can be examined by all who feel an interest in so important a subject.

Having obtained successful results in the elastic action both of wheels and rails, the next question was to obtain a true mechanical action in the movement of wheels and axles. As far back as the year 1837 the writer had sought to impress upon railway authorities the importance of radial movement in the axles, enabling them to run at a right angle with the rails, whether on straight lines or curves, and proposed various modes of accomplishing it, but he could get no attention. The railways were made in what were called straight lines, though practically crooked lines, and it was taken for granted that the coning of the wheel tires accomplished all that was wished. But in America crooked lines obtained with very sharp curves, in order to go around street corners instead of outside the towns, and a bell was suspended at the entrance, to be struck by the engine, and a notice painted on a maple slab, "Look out for the locomotive, when the bell rings." To facilitate the movement of the engine round the curves, the front end was provided with a swivelling truck, called a bogie, analogous to the ordinary under-carriage of a road vehicle, moving on a centre pin, but with four wheels instead of two, the wheels being guided by their flanges against the rails, instead of by a pole. This was so convenient, that it came into general use in America, and it was first introduced into England on the Birmingham and Gloucester line, the engines being made in America. But it was defective in principle. In ordinary under-carriages on the road, the length of the pole steadies the wheels. In the four-wheel bogie, the distance between the front and back wheels was less than the width between the rails, and, consequently, swivelling on the centre pin, the bogie was apt to run unsteadily, and drag the wheel flanges against the rails, the contact with the outer rail on curves setting the axles askew to the rails. This evil was continued on the South Devon line, where, the sharp curves necessitating

the use of the bogey, it was applied on a seven feet gauge with the wheel centres five feet apart. In addition to this defect, apparently resorted to to compensate in some measure for the fixed parallelism of the axles, it did not in any way help the skew position of the driving wheels, as the central pivot did not permit lateral movement of the bogey. To remedy this, Mr. Bissell, in America, devised a plan of removing the centre pivot from midway between the four wheels to a point between the driver and the bogey; thus the movement of the wheels became radial, or in the circumference of a circle instead of the centre. This was a plan on which the writer had built road carriages long previously, under the name of Equirotal carriages, and had proposed to apply the principle to engines. Mr. Bissell subsequently applied the same principle to engines with two-wheeled bogies, and time and circumstances having forced on the attention of English engineers the necessity for radial movement, other attempts were made to correct the defects of the bogey, and one was by providing a lateral slide as well as pivot movement to the centre. But on this plan the guidance was lost, and it was not found to answer.

Seeing that the time was approaching for more perfect machinery and for radiating axles, the writer again set to work to simplify the structure. Abandoning the truck form, or bogey, altogether, the axle-boxes were adapted to slide in curved lines laterally through the horn-plates of a rigid engine frame beneath the spring bearings. The advantages gained by this were, first, true radiation of the axle to every curve, from the straight line down to one chain and a half radius; secondly, perfect guidance and prevention of irregular movement in the wheels; thirdly, facility in axle bearings and lubrications; fourthly, the use of larger wheels than could be obtained by the bogey system.

The writer proposed to build the engine with coupled driving wheels in the centre, and with radial wheels at the ends, eight wheels in all, and so, having ample support, to dispense with a separate tender. This was so novel a plan, departing from the customary bogey system, that it was not listened to, and bogies were continued.

The writer sent a drawing to Mr. Cross, the engineer of the St. Helen's, and about nine months after received a letter from that gentleman stating that having found it necessary to use larger engines for his increasing traffic, he had studied the whole question carefully as to the best principle of radiation for his sharp curves; and having come to the conclusion that the plan of the writer was the simplest, safest, and most effective, as well as the least costly, he had constructed a model and verified it experimentally, after which he put in hand a full sized engine. (A large-sized model frame of this may be seen on the table.)

After working for some time on the St. Helen's, both for passengers, goods, and coal, and perfectly establishing the soundness of the principle, this engine, called the "White Raven," was brought to London for experiment, and examined and experimented on by a large number of railway engineers, whose judgment confirmed the truth of the principle of structure.

It was at first supposed that the free movement of the wheels would tend to make the engine unsteady on straight lines at high speeds, inasmuch as front wheels, fixed laterally in the horn plates were supposed

to exercise a steadying and governing power. But the contrary proved to be the fact. Another engine, altered from the rigid system to the radial, was found to run much steadier after the alteration, after acquiring the facility for rounding sharp curves. In truth the unsteadiness of all engines, apart from bad construction, arises from the fact that the wheels, fixed to the frame and seeking the path of least friction over uneven rails, force the frames to partake of their irregular movement; and, as might be expected, the inertia of the engine frame keeps it steady enough when the wheels are left free to pursue their own courses unshackled.

This novel arrangement comes at a convenient time, as the extension of railways through towns and mountainous countries is now the prevalent thought. But even for what are called straight lines, their extension into and through towns, and new station accommodation, renders it very important to have engines working round very sharp curves, and either end foremost. The great cost of land and the removal of buildings in approaches where only straight lines or very large curves can be used adds very materially to the cost of construction. But there is another question, quite as important. It is well known that the rapid wear of the rails of railways is very largely owing to the weight of the engines, apart from the train, and in the engines the destruction by rail crushing is increased in proportion to the weight on the driving wheels. Some engines have only one pair of driving wheels, as they involve less impedimental friction at high speeds. Some have two pairs coupled together, and some three pairs. Inasmuch as the engine draws the load by reason of its own weight on the rails giving adhesion, it follows of course that a heavy train needs more weight on the driving wheels than a light one. When a single pair of drivers are used the load sometimes approaches to fourteen or fifteen tons, and this crushes both rails and tires. If however the load can be distributed over more wheels, this destruction may be avoided. Twenty tons on four wheels is much less damaging than fourteen tons on two wheels. For this reason our continental neighbours have been aiming at two things combined—to obtain the adhesion of many wheels with the facility of passing round sharp curves. The ordinary method of coupling wheels by side rods does not admit of this, and the writer has resorted to another method, illustrated by the model on the table, which, as regards its eight lower wheels, is precisely similar to the St. Helen's engine, the "White Raven." But in addition to this, it has four other wheels, two of which are placed at each end resting between the central driving wheel and the end radial wheel on their peripheries, pressing downwards with any amount of weight needed to induce adhesion. In fact the whole weight of the engine and frame may be supported by the upper wheels if needed. But practically a comparatively small weight is needed, as the wheels do not merely rest on one another, as is the case with wheels on rails, but have also a wedging action, which may, if permitted, produce an intense pressure. All the wheels have also spring tires, which ensures elastic contact and fit, without blows. It will be seen that when the driving wheels are put in motion, they communicate that motion by friction to the upper wheels, which in turn communicate the motion to the radial wheels, and continue to do so when the radial wheels are on curves, the effect being that the axes of the upper wheels depart from the horizontal line, dipping to right or left according to the lengthening or shortening of the distance between the lower wheels on curves. And the adhesion is perfect, because the load on the upper wheels forces down the lower wheels to a perfect pressure on the rails at either end of the engine. Thus there are eight drivers which may be equally loaded and the whole weight of the engine is available for adhesion. And in reversing, for the purpose of retardation, the whole of the wheels are available. To make the machine complete, brakes are applied between the driving wheels, arranged to act both against the wheels and rails by small steam

cyliners, so that the retardation of the engine is within the control of the driver by simply turning his regulator and steam cocks, without needing the muscular force of his fireman, labouring at a screw with slow movement. It will be seen that this engine will run on S curves as easily as on regular curves.

Of course the steam power of an engine should be in proportion to the adhesion. Practically it is far in excess of the adhesion, inasmuch as sand is commonly used to prevent the slip of the wheels; and this, though useful to the engine, is a serious disadvantage in increasing the resistance of the train. This seems certainly the case on the Great Northern, where it is found advantageous to make the tender wheels drivers, as well as those of the engine, with the same boiler power.

In the early days of railways the difficulty of adhesion between a smooth tire and smooth rails was considered to be great, before it was tried. But in those days the trains were light, and the increase in weight has again drawn attention to the desirability of increasing the adhesion. Blocks on the rails and wheels might no doubt be used, as they have been, and as they are still in some collieries; but this can only be for very slow movement. Yet there is a mode of increasing adhesion not yet resorted to, but which will probably be resorted to, where the whole difficulty of mounting steep ascents, such as one in twelve, or 440 feet to the mile, shall occur on any sharp curves. It is to convert the rounded flanges of the wheel tires into two flats at an angle of 45 degrees, and enlarging them to take a corresponding groove formed in the surface of the rail. The driving wheels of the engine only are to be fitted to these grooves, and the ordinary flanges of the train wheels can easily pass, being of smaller size. It may be remarked, that it would not be easy to lay rails accurately enough for this, and especially on curves, but compensation can be easily provided by the use of spring

tires sliding laterally on the wheels, and there is no reason why the eight coupled engine before described should not work perfectly well in this mode, on sharp curves and stiff gradients. The pair of wheels on the table illustrate this principle of spring tires with angle flanges working in V grooves. The diagram on the wall illustrates this.

Thus with radial axle, spring tires, angle flanges, and elastic permanent way, several difficulties are got over. The blow and sledge movement is removed from between wheel and rail, as well as the grinding action against the flanges, and the adhesion is ensured, while the permanent way is rendered really permanent.

It may be objected to that the angular flanges will tend to wear away both tires and rails. This is quite true, but if we want to do hard work we must pay for it in some shape or other. The only question is, is it worth doing, and if so, what is the least costly method as well as the most effective and simple. We know that we can drive machinery by friction pulleys, and there is no mechanical reason why we should not drive railway trains. And these tires can be removed and replaced with perfect facility without needing workshops.

But it is not merely the question of engines that we have to deal with. It is that of carriages and wagons also. These vehicles have been kept short, and their wheels disadvantageously near together, chiefly on account of the difficulty of curves. This system needs remodelling, but there are so many considerations that it must be deferred to another paper.

DISCUSSION.

Mr. ROCHUSSEN fully agreed with the principle laid down, that in order to neutralise as much as possible the wear and tear of materials by friction, they should have elasticity, and that elasticity might easily be promoted by the improvement of materials themselves, as pointed out in the paper. There was no doubt the introduction of steel into the manufacture of rails tended to add to the durability of the rails as well as to introduce the element of elasticity to a large extent. The Bessemer process enabled them to produce steel rails at a comparatively low cost; at the same time it had not superseded the other description of steel rail which was largely used on the Continent, viz., the puddled steel rail, by which the tendency to split, spoken of in the paper as occurring in the common iron rail, was obviated, and the advantage of puddled steel was, that it welded well with iron. Thus they had a flat-bottomed or Vignolles rail, which was still used to a large extent on the continent, consisting of a head and web of puddled steel, and an iron base. The welding of the steel and iron was complete, and while this combination gave a harder surface to the tread of the metal, the elasticity of the iron was retained. He had seen the advantages of that combination of material at the Hamm station of the Cologne-Minden Railway, the traffic of which was equal to that of Cresse, where steel-headed rails with iron web and base had been in use for ten years and showed no signs of wear. Bessemer steel would not weld well with iron, and therefore it was best adapted for the double-headed rail. As far as the elasticity of rolling stock was concerned, he greatly admired the plan of Mr. Adams, of introducing an elastic material into the tire of the wheel. But he (Mr. Rochussen) would remark, that the combined steel and iron he had spoken of in rails, was also applied to wheels, and offered all the advantages of elasticity contended for. Both wrought and cast-iron discs in straight section were objectionable, whilst in a corrugated section the wheels have a power of contraction which counteracted the force of the blows; and, on the other hand, they had but little vibration laterally. The great advantage of the disc wheel was that it did not raise the dust as the spoke wheel did, and obviated the great atmospheric resistance which the fan-like motion of the spokes created. With regard to the system advocated by Mr. Adams, he would ask how it could be ascertained when the piece of *lignum vitæ* or other wood inserted between the wheel and the tire showed signs of decay, as it was completely hidden from view, and there were no visible means of knowing when it became in an unsound state. While on the subject of disc wheels, he would remark that wrought-iron disc wheels, which were much in use on the continent, were working their way gradually in this country. In the Exhibition of 1862 a manufacturer, with whom he was connected, showed some driving wheels on the disc system, which weighed $2\frac{1}{2}$ tons each, made of

cast steel, that material being considered better than wrought iron; but it appeared that wheels of that description were greatly affected by severe changes of the temperature of the atmosphere, and in one night no fewer than nineteen of those wheels cracked, while there was no instance of wrought-iron disc wheels having given way under atmospheric influences. The iron was forged from the bloom, with a hammer weighing five tons, and the cast steel tire was batted on to the T-piece of the disc, or a puddled steel tire was used and welded to the disc, and as the steel surface of the tire wore off, it could simply be turned down, and another steel tire slipped over it, but hitherto no instance of the wearing out of such a wheel had occurred. The axles were not keyed in, but pressed into the wrought-iron nave with hydraulic power.

Mr. DENNET felt much indebted to Mr. Adams for the paper he had read, but he wished that gentleman had gone a step further, and had given them a little more information as to the means of avoiding many of the risks of railway travelling. With regard to wear and tear of the line and plant, it was a question of great importance, in which the shareholders of railways were very much interested. There was an invention connected with this part of the subject to which he would call attention. The inventor of it, Mr. Jowett, he had hoped would have been there that evening to explain it, but his sudden and unexpected death within the last four days had deprived them of the valuable information which he would have furnished. The invention alluded to was a form of fish-joint, models of which were on the table for the inspection of the meeting. For this invention he had received but £12 10s., whilst it had been disposed of to a company for £21,000, and they had realised from it £80,000. Mr. Dennet then called attention to the specimen of rails, sleepers, plates, and a new fish joint, all of which were the invention of Mr. Jowett, and he pointed out the advantages of this "rail" and mode of setting as obviating two or three difficulties in railway travelling. The ordinary rail was from five to seven inches in height, and being fixed in iron chairs on the top of the sleepers, there was a vibratory motion, which gave that zig-zag movement so unpleasantly experienced by railway travellers. In the model before the meeting the rail was set in a groove to half its depth of the sleeper; there was a slot or hole cut in the rail, through which a wrought iron wedge or plate was inserted eight or nine inches in length by four or five inches in width and one inch thick, which plate was fastened to the sleepers by bolts or spikes. By this plan there was not only a saving of wear and tear of the rail but an economy in first cost. It could be adapted to rails of any material and of any shape. It could be applied to a light but serviceable rail, it dispensed with the wooden keys and chairs, and lessened the number of sleepers by two in the length of rail. The saving in the cost of laying rails was equal to £300 per mile. In India it would be found that the economy of this plan was equal to £490 per mile, or £40,000 in 100 miles, while in this country the saving would be about £28,000 in the same length of line. Mr. Dennet added that this plan had been tested during seven months on a short length of the South-Western Railway, where it could be seen by those interested in the subject.—Mr. Dennet also exhibited a form of fish-joint which he considered novel, and highly advantageous and practical.

Mr. ZERAH COLBURN, on being appealed to by the Chairman, said his observations had been confined mostly to lines in America, and, as far as his experience went, it bore out the soundness of the principles brought forward by Mr. Adams. The American lines were, for the most part, imperfectly constructed, partly from the inferior quality of the earthwork and want of ballast, and to a great extent from the bad form of rail—the common contractors' rail, with a flat foot, but of bad shape and bad quality of iron. Mr. Colburn explained the form of rail generally used, showing how the contractors' form of

rail, which could readily be fished, had, owing to the bad quality of the iron, in order to gain strength been altered into a form which did not admit of fishing. Nevertheless it was the fact that the American carriages travelled over these lines as smartly as first class carriages on the superior lines of this country. This he thought was mainly due to the use of the boggy, the great length of the carriages, and the manner in which they are hung. The boggy had the advantage of going round curves easily, and the mode of attaching the carriages to it distributed the weight more uniformly; if they met with an obstruction the shock was not imparted to the carriage. The arrangement for allowing the carriage to swing freely on the body of the boggy, as adopted in America, had been introduced on the Metropolitan Railway, where it would be noticed that the carriages have a peculiarly easy motion. Mr. Adams had spoken of the boggy as having been originally invented in America, but he believed it was first introduced by Mr. Chapman, of Newcastle, in the year 1812, and was first used there. It was taken up in America at an early period, and had continued in general use ever since. It was the opinion of some locomotive engineers in this country that the use of the boggy to engines and tenders was not so safe as placing the wheels in the ordinary manner. He thought that was a mistaken opinion. He had designed some rolling stock for one of the Brazilian lines, and in opposition to his advice the boggy was dispensed with; but experience in the working of heavy gradients and sharp curves led to the ultimate adoption of the boggy. With regard to elastic wheels, something on the principle described by Mr. Adams had been used with success in the States of America, but not of the form which that gentleman had described.

Mr. DENNET inquired whether Mr. Colburn could give any information as to the description of wheel in use on the Massachusetts line, which he had been informed had resulted in great economy of wear and tear.

Mr. COLBURN was not acquainted with the kind of wheel used on the line mentioned. He apprehended it would be something similar to those on the South-Eastern line in this country, viz., segments of wood put together. He would, however, add that one objection to the boggy was the necessity it entailed of using wheels of small diameter. A larger diameter than three feet was never used. As a rule the carriage wheels were 2ft. 9in., and the engine wheels 2ft. 6in., and for goods engines only 22 inches. The plan of Mr. Adams enabled a much larger wheel to be used, and this was, in his opinion, a decided advantage.

The CHAIRMAN said there was no doubt Mr. Adams had introduced a very important subject for discussion that evening, advocating, as he did, a radical change in the construction of our railways and the rolling stock. On the first introduction of railways he had no doubt it was in the recollection of many that a very rigid road was made. In the first instance the rails were laid on chairs fixed into stone blocks, and on one line, he believed in the north of England, they actually built brick walls, on which they laid the rails. All those arrangements caused the rails to be knocked to pieces very soon, and engineers then resorted to wooden sleepers laid upon ballast. The Great Western Railway was, in the first instance, constructed by Mr. Brunel by laying longitudinal sleepers on piles driven a considerable depth in the ground, but at the points where these piles supported the longitudinal bearings great injury resulted. These piles were consequently all removed. The system was changed, and the sleepers were laid simply upon the ballast. This, therefore, appeared, to be the great object at which railway engineers were aiming in order to avoid or mitigate the shocks produced by railway trains. He therefore thought no one would be disposed to object to a trial of the plan proposed by Mr. Adams. To him (the chairman) it seemed a most reasonable plan; but, of course, in railway experience it would not be prudent to express any very

decided opinion upon a new principle of construction until it had been tried for a considerable time. The arrangement which Mr. Adams proposed for making the tires revolve on the wheels was certainly new. It had been tried, and was a great advantage. It had long been sought by railway engineers to make the wheels revolve upon the axles. The principle of Mr. Adams was very much to the same effect. It made the periphery of the wheel the point at which the revolution took place instead of on the axle. With respect to the fish-joint which Mr. Dennet had claimed for Mr. Jowett, he believed there were a great many persons who laid claim to its invention. He knew that Mr. Adams put in claims for that many years ago, and he knew many others who also laid claim to a mode of fishing rails. He had no doubt that by Mr. Jowett's plan a certain amount of elasticity would be obtained, but Mr. Dennet had not stated whether the sleepers themselves would not be weakened by that arrangement.

Mr. DENNET replied—Not at all; quite the reverse. He would add that he did not claim for Mr. Jowett the invention of the fish-joint, but that particular form of fish-joint to which he had referred. It was different from that of Mr. Adams's, the ingenuity of which he did not wish to detract from.

The CHAIRMAN said he remembered a system of fixing the rails into timber as long as twelve years ago—not exactly like that shown to-night, but very similar to it, which was tried on the South-Eastern line near London-bridge.

Mr. DENNET said that Jowett's plan of fixing the rail in the wood was different from that alluded to by the Chairman, and was quite new. In the plan referred to by the Chairman the metal was embodied in the wood.

The CHAIRMAN then proceeded to say that these various proposals of Mr. Adams undoubtedly tended to diminish a very great amount of the friction which took place in railway trains: and any diminution of those forces would practically be a diminution of the cost of working, and an increase of dividends to the shareholders; and he trusted it would eventually lead to a diminution of the fares charged to the public. In that respect these matters were of the greatest public importance, and he was sure the meeting would readily accord their thanks to Mr. Adams for his very able paper.

The vote of thanks having been passed,

Mr. ADAMS said he took no credit to himself for the invention of the fish-joint, for five hundred different people, setting down to patch a rail as he did in the first instance, would probably have come to the same conclusion, only he happened to be the first to place such an invention on record. He never considered the fish as used was good, and he set himself to devise what he thought was a good fish on the plan he had laid before them. With regard to wheels, he did not enter into the question of which was the best structure, but merely alluded to the disc wheel as a form to which he wished the elastic tires to be applied; but the spring tire was applicable to all kinds of wheels, whether on common roads or on rails, and the section on the wall showed a mode of applying spring tires to road locomotives. The subject was too extensive to be dealt with in one paper, and he would deal with other branches in the paper which was to follow. He wished, however, to impress upon the meeting that it was perfectly practicable to make engines to go round curves of a radius of $1\frac{1}{2}$ chain, and he claimed a plan of distributing the weight upon all the wheels of an engine instead of principally upon the driving wheels. As to the mode of fixing the rails in the sleepers, there had been several plans proposed of cutting the sleepers, but they were all open to the objection that by cutting into the material of the sleeper its strength was impaired. If a sleeper with the ordinary chair required five inches in depth, then when it was cut away to the depth of three inches, it ought to be eight inches in depth in order to make up for the part cut away.

Proceedings of Institutions.

WORCESTERSHIRE UNION OF EDUCATIONAL INSTITUTES.

—The annual meeting of this body was held on Wednesday, the 16th November, at Droitwich. The proceedings consisted of a morning meeting for business and discussion, a public dinner, under the presidency of Lord Lyttelton, a *soirée*, and evening meeting. The evening meeting was held at six o'clock, and was attended numerously, many ladies being present. The chair was occupied by Sir John Pakington, Bart., K.C.B., M.P.; and there were present on the platform Lord Lyttelton, Lord Robert Cecil, M.P., the Hon. and Rev. W. Douglas, the Rev. Canon Melville, Rev. Dr. Collis, Rev. W. Walters, Mr. H. F. Vernon, M.P., Mr. J. S. Pakington, the Mayor of Droitwich (Dr. Roden), Mr. J. S. Isaac, and others. The chairman, in opening the proceedings, said he was delighted to bid welcome, in the name of the Droitwich Institute, and of the whole neighbourhood, to the representatives of the different Institutes forming the union. He believed that there was no nobler object of domestic policy in this country than the endeavour to promote everything which could tend to improve the physical or the intellectual condition of that vast body of their fellow countrymen who lived and maintained their families by their own exertions and their own industry. The more they elevated the character of the working man, the more they increased his respectability and comfort. The more closely they could draw together those various classes of which English society was composed, and bind them closely to each other by feelings of mutual respect, mutual dependence, and mutual good feeling, the greater would be the aggregate of the prosperity and the happiness and the welfare of this nation. These were considerations which induced him to attach the greatest possible importance to meetings of that kind. They were assembled there essentially and specially to promote a great public object, which, in his judgment and belief, referred essentially and directly to the welfare of those industrious thousands by whom they were surrounded, but their immediate object related to the intellectual improvement of those classes. He here wished to say, in the most distinct and emphatic manner, that he would not ask them to support that union, he would not ask them to give to the Institutes separately their best aid, if he did not in his conscience believe that they were calculated to promote clear, distinct, practical benefits. Looking to the manner in which these Institutes promoted the interests of the working man, they did so in two distinct and most important respects. The first he would advert to was this: that they sought by these Institutes to give to the industrious working man a resort where, in his leisure hours, he might enjoy innocent and useful recreation, instead of being driven to the dangerous and seductive enjoyments which were offered by the public-house. If any publicans were present they would forgive him. He did not wish to interfere with their legitimate business, but what he wanted to say was, that the working man should be able to resort to an Institution where he might obtain innocent society and innocent recreation and amusement, without the danger of being enticed into habits which must be destructive of his own welfare and of the welfare of his family. The next object was of immense importance—that they might, by resorting to these Institutes, avail themselves of the educational classes which always ought to be carried on in connection with them. He was glad to find that nearly all of the 20 or 30 Institutes in the union had educational classes in connection with them, and that their progress had been steady and rapid since 1858. Sir John concluded by expressing his belief in the good which was effected by the organisation and system which this meeting of the union every year enabled them to carry out.—The secretary having read the report, Lord Robert Cecil moved—"That the continual education of

the industrial classes after the age of childhood was one of the most important aids to national well-being, and, as such, deserves the best attention of statesmen and philanthropists." The Rev. D. Melville seconded the resolution, which was carried. Lord Lyttelton and other gentlemen afterwards addressed the meeting.

NORTH LONDON WORKING CLASSES INDUSTRIAL EXHIBITION.

The following is the report of the adjudicators:—

The duties undertaken by the adjudicators, at the request of the committee, were of great delicacy; and the experience acquired by them in the Exhibitions of 1851 and 1862 in London, and of 1855 in Paris, helped them less than might have been expected, as the different circumstances under which the articles exhibited had been produced and collected rendered any previous standards of comparison inapplicable. The present Industrial Exhibition, like that recently held at Lambeth, has but little in common with those great undertakings. On those occasions considerable time was given to the public for preparation; temptations to exhibit were freely offered in the shape of medals and other prizes; for a prominent manufacturer to fail to be represented, was to "go to the rear" in the great industrial race; the opportunities for comparison and competition were beyond all precedent; capital had ample scope for profitable investment in productions suitable for sale in the markets of the world; and above all, these Exhibitions were inaugurated by the patronage and presence of the most illustrious personages of this and other countries—by splendid pageantry and ceremonial, and by profuse expenditure in decoration, music, and other attractive accessories. "The North London Working Classes Industrial Exhibition," from its necessarily limited nature and modest pretensions, can lay claim to no such advantages; it is emphatically a Workman's Exhibition.

The original idea, the organisation, and the successful results, are solely due to working men as exhibitors, committee-men, and honorary secretaries. They have declined many tenders of pecuniary assistance from the wealthy, but have not hesitated gratefully to accept spontaneous offers of guarantee from well-wishers to the experiment, in the full confidence, now happily more than realised, that the necessity for having recourse to them would not arise.

The response on the part of the workmen to the invitation to exhibit was enthusiastic, and resulted in a contribution of several thousand miscellaneous articles, upon the merits of which the Adjudicators have had to form a judgment. In making the awards, the merits of professional work have not been brought into competition with those of that produced by amateurs; but the Adjudicators have endeavoured, in all cases, to take into reasonable consideration the circumstances under which the articles have been elaborated. As regards professional workmanship, much of it is highly creditable to the producers, especially considering the nearly extemporised circumstances under which their skill and taste are exhibited in so many forms. As regards the amateur contributions, the Adjudicators are of opinion that, taking into consideration the small amount of leisure, and, in many cases, the inferior appliances and limited means at the disposal of this producers, the articles exhibited show in many instances a high, and in some instances an extraordinary degree of merit. It has afforded sincere pleasure to note the elevating character of very many evidences of the substitution of intellectual cultivation, in the workman's hours of relaxation from his daily and appointed toil, for the grosser stimulants of the senses. Such illustrations of successful aspiration are regarded as elements of even greater hope for the future than they are of congratulation for the past.

The adjudicators cannot close this Report without

tendering their warmest congratulations to the Committee and others who have organised in their district this most successful social experiment, and can only regret that the limited time for which the Hall was available has rendered it necessary to close the Exhibition whilst the continued attendance of very large numbers seemed to show that the interest excited was undiminished.

M. DIGBY WYATT.

14 November, 1864.

WEST LONDON WORKING CLASSES' INDUSTRIAL EXHIBITION.

On Monday evening, the 21st November, a public meeting was held in Castle-street school-room. Mr. R. M. MORRELL presided, and, upon opening the meeting, said he believed that the objects of industrial exhibitions were now so generally known that it would require but little explanation from him. He felt confident that much good had arisen from those exhibitions that had been already held, and as the north and south of London had successfully held their exhibitions, he (Mr. Morrell) contended that it would be an utter disgrace to the working men of the western division of London if they did not make as good, if not a better, exhibition than those previously held. After reading the preliminary prospectus and commenting upon the names of the several gentlemen who have already consented to be parties to the guarantee fund, he left the proceedings entirely in the hands of the meeting. It was then moved by Messrs. Howe and J. B. Bailey, "That this meeting pledges itself to support the Industrial Exhibition for the borough of Marylebone that is now in course of formation all that lies in its power." After which Mr. Tucker proposed, and Mr. C. Hooper seconded, "That a district committee be formed from this meeting for the purpose of making the movement known and obtaining patrons from members of this district," which was also carried. A working man then asked whether the committee of the exhibition would guarantee the registration of any new invention that would be exhibited. The chairman, in answering, said that as the committees of those exhibitions which had already been held (he believed) did not feel themselves safe in promising to guarantee a registration to any exhibitors of a new invention, he thought his committee would take the same view of the question, but he would accept the feeling expressed by the meeting as an instruction for him to put himself in correspondence with the committees of the past exhibitions, and would consult a member of the Government as to the desirability of introducing a short Act of Parliament which should give the desired guarantee of security to all future exhibitors. The assistant secretary, Mr. S. A. Barrows, then said that he thought it would be unfair to the parties to the guarantee fund for the committee to promise to guarantee registrations, at all events for the first exhibition, but as it was decided to invest any surplus that might arise from this exhibition in the names of trustees for the purpose of defraying the expenses of any future exhibition that might be held in the west of London, he thought that if it should be decided that the committee could not guarantee registration on this occasion, they might be able to do so on the next. Mr. C. Hooper then asked what prizes it was intended to award. The chairman said that he was extremely sorry that the committee did not feel themselves in a position to promise pecuniary prizes, but undoubtedly if this exhibition proved as successful as the north of London, they would distribute part of the returns in prizes, and invest the surplus. Mr. Foxwell, a working man, addressed the meeting at some

length on the subject of the guarantee fund. He said that he would be sorry to object to the upper classes assisting the projectors in so excellent a movement, but he considered that working men themselves should figure largely in the guarantee fund. He should like to see every working man in the west of London, and indeed all others who take any interest in such a movement, guarantee some sum, if only a shilling, but he also hoped that although the committee might have many names on their guarantee fund, there would be no necessity to call upon one of them. He then moved the following resolution, which was seconded by Mr. Haswell, and carried amid loud cheering:—"That working men present pledge themselves to support the guarantee fund of themselves as far as lies in their power." The assistant secretary then received the names of the working men present for sums varying from 10s. to 2s. 6d. A district committee of eight, with power to add to their number, was then formed, and after a vote of thanks to Mr. Charles Marshall for the use of the room, the meeting concluded with a vote of thanks to the chairman.

Manufactures.

TEXTILE MANUFACTURES.—From an official account just published by the Minister of Agriculture and Commerce at Turin, the raw silk brought into the markets of Italy during the last year amounted to upwards of 4,000,000 lbs., representing a value of about 4½ millions sterling. The quantity of cotton spun in Italy was above 60 million pounds weight, more than half of which belonged to Lombardy. The quantity of flax sent during the last ten months to the port of Archangel alone from the province of Vologda was about 18 million pounds weight. There are 49 cloth-manufactories at Moscow, producing £1,663,000 worth of cloth. There are besides 90 manufactories of thin woollen stuffs, which have in a great measure superseded cotton ones, owing to the scarcity of that material.

LENOIR'S GAS ENGINE.—This engine, a notice of which was given in the *Journal*, Vol. XII., p. 673, is being largely used in Paris. It is said there are not less than five hundred now at work in that city for various purposes, and amongst others it is employed by builders for hoisting their materials. The one which was put up in Birmingham a short time since by Mr. Wiley at his factory is reported a success. A manufactory of these engines has just been established at Reading.

Commerce.

EXTERNAL TRADE OF THE COUNTRY.—It is well known that the trade of this country has been advancing of late years to an enormous extent, notwithstanding the American war and the unsettled state of European politics. This advance is shown in a striking manner when the Board of Trade returns for the past ten years are compared. The total increase in the trade of the country in that period is nearly £177,000,000, which is made up as follows:—Imports, 1854 £162,389,000

" 1863	248,981,000
Exports, 1854, British produce	£97,184,000
" " Foreign and colonial	18,637,000
Total	£116,821,000
" 1863, British produce	146,489,000
" " Foreign and colonial	49,485,000
Total	£195,974,000

The total imports and exports of the country, which

were £268,210,000 in 1854, had risen to £444,955,000 in 1863. The increase in importation (£96,502,000) is enormous, but is not of such importance as the figures would at first indicate, since a large proportion is again exported, this country serving merely as an entrepôt, but it affords a very valuable index to the prosperity of the country when we find that it has been followed by proportionately increased consumption. The quantities of corn and flour, the most important articles of consumption, have nearly doubled in the ten years, whilst cotton, 40,000 tons of which came here in 1854, rose in 1860 to 60,000 tons, but it declined to 30,000 tons in 1863, in consequence of the American war. The consumption of wine has increased about twenty per cent.; tobacco to about the same extent; tea, currants, raisins, and other dried fruits have greatly increased; whilst coffee and cocoa have alone fallen off. Sugar has, considering the increased prosperity of all classes, virtually stood still.

BANKING IN FRANKFORT.—The banking business is the most important in Frankfort; indeed, the city possesses nearly as many banking firms as there are persons employed in banking and gold dealing in Bremen, and absolutely more than the number of such establishments in Berlin. There are 99 directors, or heads of banks, in Frankfort, who employ 383 servants, 203 clerks, 150 apprentices, and 144 travellers. The banking business sustains directly nearly 2,000 persons in all. There are also 183 money-changers.

GRAPES FROM THE UNITED STATES.—Fresh-grown grapes have been shipped from New York to this country, by way of experiment, to Messrs. Keeling and Hunt, of London.

Obituary.

M. ACHILLE LEFEVRE, a French engraver, who has reproduced the principal works of Raphael and Corregio, and whose "Antiope," ordered by the Imperial Government, was exhibited the other in the Palais de l'Industrie, was carried off rather suddenly a few days since. His death is a severe loss to art.

ANOTHER vacancy has occurred among the Royal Academicians by the death of David Roberts, which occurred suddenly on Friday evening, the 25th of November. He had just completed the 68th year of his age, having been born in the neighbourhood of Edinburgh, on the 24th of October, 1796. While a boy he was apprenticed to a house painter in Edinburgh, and during that time admitted to the Trustees' Academy, in which Wilkie, Allan, and many other Scottish artists were reared, but only attended once. Coming to London, we hear of David Roberts as engaged as a scene painter at Drury-lane Theatre, where he commenced his career in 1822, along with the firm friend of his early and later years, Clarkson Stanfield. Shortly after he and other artists instituted the Society of British Artists, of which he was for some time vice-president. He first exhibited at the Royal Academy in 1826, when he sent a view of Rouen Cathedral, and in the following year he exhibited one of St. Germain's, at Amiens. His name does not, however, appear in the Academy catalogue again until 1830. After another interval, in 1835-6-7 he contributed views of Spanish antiquities, and in 1839 he was elected an associate, attaining the full honours of the Academy in 1841. Roberts was always a great traveller, and he has been for the last quarter of a century a very copious contributor of views of Egyptian, Belgian, Spanish, and Scottish architecture and scenery, as well as subjects from Venice, Vienna, and other Continental capitals. His "Inauguration of the (first) Great Exhibition" was a commission from her Majesty. We look back with wonder on the production of works of such quality—"The Baalbec," "The Jerusalem from the Mount of Olives," "The Temple of the Sun at Baalbec," which our readers will remember at the International Exhibition of 1862, and "The Destruction of Jerusalem." Among the

principal works illustrated by him were Sir Edward Bulwer Lytton's "Pilgrims of the Rhine" and the "Landscape Annual" for 1835-6-7-8, embracing views principally in Spain Morocco, Castile, Andalusia, and Biscay. The best known of all his works is his "Sketches in the Holy Land, Syria, Idumæa, Arabia, Egypt, and Nubia," in four volumes folio, with letterpress by Dr. Croly—one of the largest and most important works of the kind ever published in this country. Very many of Roberts's best paintings have been engraved, and to this fact is due some portion of the wide spread reputation of his exquisitely gifted and graceful pencil. Mr. Roberts took an active part in the proceedings of the Society of Arts connected with its exhibition of living artists. Mr. Roberts was married, and has left surviving issue. In private life he was sincerely and deservedly beloved, both within and without the profession of which he was so distinguished a member. He was elected a member of the Society of Arts in 1847.

Notes.

BRITISH MUSEUM.—A notice has been posted in the reading-room of the British Museum, intimating that a refreshment-room has been provided, under certain regulations, for the exclusive use of readers and students. This concession will doubtless be appreciated by many who have for a length of time suffered great inconvenience by being compelled to rise from their studies and leave the institution to obtain refreshments.

LIGHTING MOSCOW WITH GAS.—In the *Hague Dagblad*, it is stated, that M. N. D. Goldmanid, of this town, has acquired a concession for lighting Moscow with gas. It is granted for 30 years, and gives him an exclusive privilege of laying gas pipes and other fittings in the streets of Moscow for that time. The number of public gas-lamps is to be 10,000, and private buildings will require 150,000 lights. Moscow has more than 400 hotels and 3,000 coffee-houses, inns, and ginshops; these are open all night, as the inhabitants seldom go to bed before 2 or 3 in the morning, and in the winter scarcely ever remain in the street. The number of shops and magazines is four times greater than in St Petersburg. According to the terms of the contract, the gas will cost for the private lighting 5 roubles, or 9s. 50c. per 1,000 cubic feet (English measure). The concession will require colossal gasworks, but there can be no doubt it promises in a financial point of view good results.

NEW LABORATORY FOR DR. HOFMANN AT BERLIN.—The *Moniteur Scientifique* announces that the Prussian government has bought a plot of ground at Berlin on which to build a large laboratory for Dr. Hofmann, who will leave London soon and commence his university course of lectures there after next Easter. Dr. Hofmann, however, will, when the laboratory at Bonn is finished, definitively take up his residence in that city. The first stone was laid with much ceremony on September 16.

CO-OPERATION IN PARIS.—A number of working coppersmiths of Paris are now forming a society for the foundation of a firm to be conducted by the members themselves in common. A capital of 25,000*fr.* has already been raised by 250 shares of 100*fr.* each, subscribed by 208 workmen. The intention of the association is to gradually unite as many members as possible of the trade as associates in workshops to be successively added to the establishment.

FIRE ARMS.—The official life of the Enfield rifle is 12 years, and during this period it is calculated to fire about one thousand rounds, as each man is allowed 80 rounds a year. At the end of 12 years the man is entitled to a new rifle, but as many of the volunteers who practice assiduously at shooting, and fire more than a thousand rounds in a year, the Enfield in their hands cannot be relied on after a twelvemonth's use. It is, in fact, worn out at the end of that time.

Correspondence.

MR. FAIRBAIN'S PAPER.—**SIR,**—In your report of the discussion following Mr. Fairbairn's lecture on iron, you have made me appear to advocate the use of steel armour-plates. This is not correct. I distinctly stated that whilst it efforts to produce efficient steel armour had failed, that mild steel was a 'miraculously adapted for the heavy war, and internal plating of men of war.' However, that it was only a question of the application of proper roll bars and frame-girders in one; solid built steel of building them up, by rivetting a system of I and angle bars; and that a better material, applied in the best form, would enable us to save from 50 to 60 tons in the weight of our armour-cessed types. Apologizing for this short intrusion,
I am, &c., F. A. ROOPEMAN.

17, Queen's Chapel, London, E.C.,
23 November, 1864.

IRON-CLAD CONSTRUCTION.—**SIR,**—In my notes on the first construction of dwellings published in *Journal of the Society of Arts*, I have omitted to mention amongst the plans a plan designed by Mr. F. H. Groves, of 25, City Road, in the fan vault principle. The rings, separated from each of the piers, proved concentrically as plain as the others, when a circular opening was left in the centre for light, or closed with herring-bone by circumstances require, or, where more light required, panels may be formed as shown in model. The construction entirely obviates the necessity of thick masonry from the pier, as the thrust is concentrated on the angle of support. The space occupying little more would be required for a wool floor with girders and dog joints. Mr. Groves estimates that a half-brick wall will suffice for spans from 10 to 12 feet, one brick 12 to 20 feet, and one and half brick from 20 to 40 feet. He has put his principle to the test by having a wall erected in the yard of Mr. Allen, builder, of 25 South-street, Westminster, which has stood for six months without showing the least defect. The wall is 20 feet long by 11 feet wide, and consists of two panes—one illustrating a floor and roof and the second with ribs and spaces or panels left open for light. The floor has been tested with a permanent load of two tons. The cost of this construction, in a small warehouse erected on this principle, near the river, was as follows:—Revolving centering for elliptical arches, 30s. per square; for elliptical arches, brick arches, laid in revolving rings, for nine arches, 4s. extra; 14 arches, 11 2s. 6d. extra per rod on the wall-work for walls. Taking the above prices as the basis of calculation, the cost of a square, or 100 feet square, of 14 feet, would be nearly £7 10s., including leveling up the floor and tiling, and plastering outside. Further particulars as regards this construction can be seen by reference to the *Builder* journal, 27th, 1861, and May 7th, 1861. A small model has been seen at Mr. Twining's Museum at Twickenham.
I am, &c.,

ALBERT M. EYTON.

RE-ARMED GUNS.—**SIR,**—Mr. Fairbairn concludes his paper following the discussion of his paper, read at the 17th of Arts on the 23rd ult., with these observations:—the question of armour-plates he would say, if they to have 300 or 400-pounder guns, it was a question him whether it would not be better to be without the plates altogether, and let the shots go right off, because they were limited to a certain thickness weight of plates; and if they were to cover vessels, stem to stern, and five feet below the water-line,

they would not be able to carry plates that would resist large guns. If that description of artillery was used his opinion was they would have a more secure and better navy without the iron plates than with them." Why are we "limited to a certain thickness and weight of plates?" and why also are the ships unable to carry plates that would resist those large guns, if the vessels are covered from "stem to stern and five feet below the water-line?" If the Admiralty would take my humble advice and put the *Warrior*, now about to undergo certain alterations, into a dock, after removing the machinery, boilers, internal fittings and lower masts, and cut her into two—fore and aft—up the middle and separate the two sides of the ship so severed some 18 to 20 feet asunder, and convert her into a double-ended ship, those gentlemen who are inclined to despond over the present state of matters in connection with iron clad ships would then see some cause for taking fresh courage and go forward instead of backward. The *Warrior*, as she now is, is a very long ship for one of those liners which have got to do the heavy work of a sea fight. She is 380 feet in length, and only 68½ feet outside beam, drawing 24 feet water ready for sea. She is a vessel having what we may call a sharp bottom, her midship section showing a good rise of floor and a round easy bilge, with fine long tapered ends. This form of bottom tends to crankiness, and who will venture to say the *Warrior*, carrying some 1,000 tons of solid iron on her top-side, is not crank and liable to dangerous rolling in bad weather? By altering this ship, as proposed, into a double-ended ship, we shall add some 30 to 40 per cent., at least, to her present displacement; she will be stiff and able to carry, at all times and under all conditions of weather, the heaviest load in the shape of armour and guns that the progressive state of the gun question may demand. Rolling, pitching, and scudding or plunging, as now experienced in the case of our iron clads, will not exist. She would be able to meet or attack a foe when no other iron clad could attempt it; in fact, she would be just such a ship as we now require to take the place of the old wooden three deck liners now becoming obsolete. Our ships need protection in winter weather as well as summer; but we have no ships as yet adapted so well to perform this service as the old wooden liners and frigates. We have got to apply the double propeller principle to these large ships of the navy, and also the double rudder; they want something more than a single screw or a single rudder to govern their motions. And ships of this class, having plenty of room upon their upper deck, should have a battery amidships carried upon this deck over the engines, and boilers protected with plating or other armour, to protect it against vertical fire as well as horizontal fire, which battery could be armed with six or eight heavy guns upon turn-tables, the extremities of this deck having turrets. We should then have a most formidable ship, not intended to run away from the enemy, but to stand her ground, and calculated to receive him and return his compliments most vigorously. There are no difficulties in our way of cutting the *Warrior* or any other iron-clad ship, which is found to be too narrow, into two parts, fore and aft, and separating them any required distance apart, which may not be overcome; and this is certainly the best way to spend our money at the present time, to put the most for it—far more wisdom in it than continuing to build ships to carry permanent armour after the present style of model. We know as much as we need to know at present in regard to "the application of iron to the purposes of naval construction;" but we evidently are far astray in the models and proportions of our ships, propellers, and steering apparatus, and other matters bearing upon this part of the subject of armour-clad ships of war. Mr. John Hawkshaw's remarks on the question of armour are worth particular attention.—I am, &c.,

JOHN KENNEDY.

Patents.

From Commissioners of Patents Journal, November 25th.

GRANTS OF PROVISIONAL PROTECTION.

- Accidental fire, apparatus for giving alarm in case of—2500—W. Gilbert, E. Cooper, and G. R. Webster.
 Boots, &c., apparatus for stamping—2736—A. J. Fraser.
 Boots and shoes—2774—J. Okey.
 Bottles, stopper for—2787—F. Lane.
 Boxes, packing for stuffing—2766—R. A. Brooman.
 Card covering—2635—J. Farrar and J. Farrar.
 Carriage doors, attaching the inside handles of—2728—E. J. Harrison.
 Casting, making moulds for—2807—J. Kinniburgh.
 Cement—2801—W. L. Lees.
 Centrifugal pumps, portable—2761—C. T. Burgess.
 Cigars—2730—H. B. Harris and J. P. Thomson.
 Corn, apparatus for grinding—2768—J. Hurt and H. Tonge.
 Crinoline skirts—2849—J. N. Smith.
 Drains, &c., construction of traps for—2782—S. C. Reed.
 Files, &c., machinery for grinding—2859—R. Allinson and H. Lea.
 Fires, extinguishing—2895—C. Brothers.
 Fire-arms, breech-loading—2855—T. Restell.
 Fog signals, apparatus for producing—2813—E. Richardson.
 Food, cooking—2732—F. L. Bauwens.
 Forks and spoons, apparatus for cleaning—2805—J. Cockshott.
 Furnaces, blowing—2758—J. M. Stanley and J. Stanley.
 Gas, regulating the supply of—2827—C. Espin.
 Gases, apparatus for generating combustible—2734—F. Yates.
 Grease, obtaining from wash waters—2814—G. E. Donisthorpe.
 Gun cotton, manufacturing compounds of—2876—A. Parkes.
 Hats, manufacture of—2851—C. Vero.
 Hata, &c., manufacture of—2720—E. T. Hughes.
 Hydraulic presses—2764—A. Steven.
 Inkstands—2722—E. G. Brewer.
 Jute, preparation of—2861—F. C. Parker.
 Ladies' dresses—2833—G. Needham.
 Lamps, means of supporting glasses, &c.—2586—A. Clavel.
 Lead, extracting silver from—2776—A. Moreau.
 Liquids, apparatus for drawing off—2766—R. Kimmer.
 Looms for weaving—2829—P. A. Le Comte de Fontainemoreau.
 Metal blanks, manufacture of—2729—J. Dodge.
 Metals, machinery for punching, &c.—2726—W. Bayliss.
 Motive power by capillary attraction—2648—J. E. F. Ludeke and D. Wilckens.
 Mouldings, &c., cutting wood into—2867—H. Grafton.
 Oakum, manufacture of—2782—D. Cullen.
 Oil lamps, construction of—2740—J. Sullivan.
 Paper, embossing or indenting—2742—J. R. Crompton.
 Pipes, &c., moulds for casting—2845—G. Robinson.
 Pottery, manufacture of—2785—T. L. Boots and R. Boots.
 Printing machines—2750—G. Duncan.
 Railway carriage, lubricating axles of—2837—J. M. Hart and R. Purkis.

- Railway bars, &c., construction of—2747—J. D. Young.
 Railways, permanent way of—2795—H. Brockett.
 Railway signals, securing the levers used to work—2857—R. Holiday.
 Railway trains, safety apparatus applicable to—2724—J. G. Rowe.
 Roadways, machinery for rolling—2577—M. Henry.
 Rotary engines—2644—W. Clark.
 Saccharine matters, preparing—2538—R. Wright.
 Scarfs—2847—G. C. Attree.
 Screw driving, &c., tools for—2731—F. S. Gilbert.
 Screw propellers, method of raising—2771—W. K. Hall.
 Sewing machines—2817—J. Keats and W. S. Clark.
 Ships' sails, fitting—2663—W. Congalton.
 Shutters, rolling and revolving—2885—H. Grafton.
 Sound, apparatus for softening and deadening—2809—F. Fearon.
 Steam, &c., obtaining motive power from—2738—M. P. W. Boulton.
 Steel and iron, manufacture of—2839—J. Firth.
 Straw hats, strengthening the brims of—2778—J. D. Welch and A. P. Welch.
 Sulphuric acid, manufacturing—2607—A. Reynolds.
 Threshing machines—2718—S. Davies.
 Tramways, securing—2812—G. E. Donisthorpe.
 Washing machines—2815—J. Thorne.
 Whips, &c.—2823—C. S. Cadman.
 Wool, &c., machinery for combing—2642—G. E. Donisthorpe.
 Wool, &c., sprinkling liquids over—2744—M. J. Roberts.
 Yarns, preparing wool and hair for—2825—H. W. Kiple.

INVENTION WITH COMPLETE SPECIFICATION FILED.

- Brick and tile making machinery—2879—W. Snell.
 Ornamental chains, manufacture of—2873—G. T. Bousfield.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

Dec. 14.—“On the Recent Progress and Present State of Industry in Ireland; and the Dublin International Exhibition of 1865.” By Sir ROBERT KANE, F.R.S. On this occasion Lord DUFFERIN will preside.

Dec. 21.—The Articles sent in Competition for the Art-Workmanship Prizes will be Exhibited, and a Report in connection therewith will be read.

CANTOR LECTURES.

“ON THE REPRODUCTION OF NATURAL FORMS BY ART AND MANUFACTURE.” By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

Dec. 12TH.—LECTURE I.—INTRODUCTORY:—On the nature and probable influence of museums of natural history and art collections, and their effect on the public mind and taste. (Illustrated.)

Dec. 19.—LECTURE II.—Demonstrations of the unity of plan in the external forms of animals, the just appreciation of which facilitates the work of the artistic producer, and adds to the enjoyment of the intelligent possessor of works of art.

JAN. 16TH, 1865.—LECTURE III.—On the varieties of artistic treatment of the forms of animal and vegetable life—pictorial representation; conventional ornamental, allegorical, and symbolic combinations of animal forms.

JAN. 23RD.—LECTURE IV.—On the fitness of designs, and their adaptation to the conditions of the materials in which they are to be produced. (Demonstrated by metal-work processes, sand-moulding, casting, and chasing).

JAN. 30TH.—LECTURE V.—On Ceramic Manufactures, with the Influence of the material on the design and its successful production—modern Terra Cotta, Della Robbia ware, Majolica, and Parian.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture. A

set of tickets for this purpose has been sent to every member.

ART-WORKMANSHIP PRIZES.

Articles (ninety-six in number) sent in competition for the Art-Workmanship Prizes, have been received from seventy-three competitors, and will be arranged for exhibition in the Society's rooms on and after Wednesday, the 21st instant.

STETTIN GENERAL EXHIBITION OF INDUSTRY.

The Board of Trade have sent to the Council the following information from H.M. Consul at Stettin, in reference to this Exhibition:—

The exhibition is under the patronage of H.R.H. the Crown Prince of Prussia, and will open, simultaneously with the exhibition of agricultural products, in May, 1865. The following committee, consisting of Messrs. Dr. Delbrück, Director of Cement works; Hobrecht, City Architect; G. Müller, Belgian Consul; R. Müller, Director of Sugar-works; Th. von der Nahmer, bookseller; Rahm, Councillor of Commerce, President of the Chamber of Commerce; Dr. Scheibler, chemist; Stein, Director of the Berlin Stettin Railway, appointed by the Polytechnic Society of Stettin, has been entrusted with the management of the exhibition and has issued the following conditions:—1. Exhibitors of all nations and products of all countries are admitted. The committee is, however, authorised to refuse articles of inferior quality or minor importance. 2. The exhibition will be opened on the 15th of May and closed at the end of June. 3. The exhibitors are requested to forward a specification of the articles which they intend to exhibit, as well as of the space required for them, to the undersigned committee before the 1st of January, 1865. 4. In order to defray part of the expenses a charge will be made, the amount of which will be calculated according to the value of, and the space occupied by, the exhibited article. In respect to space, the charge per square foot, either of the floor or walls in the building itself, will be 2½ sgr.* In respect to value, for articles under 49 dollars, a charge of 10 sgr.;

* 10 sgr. equal to 1 shilling. 1 dollar equ

for articles from 50 to 149 dollars inclusive, 20 sgr.; for articles from 150 dollars and upwards, $\frac{1}{2}$ per cent. of the value. Articles of considerable size, as machines, carriages, &c., which will be exhibited in the side-wings, pay but one-half of the above mentioned charge. For instance, for an article worth 25 dollars and occupying 6 square feet, 25 sgr. will be charged, viz., 10 sgr. value and 15 sgr. space. The charge for an article worth 300 dollars and occupying 16 square feet, would be 2 dollars, 25 sgr., viz., 1 dollar 15 sgr. value, and 1 dollar 10 sgr. space. For machines worth 2,000 dollars and occupying 80 square feet, which will be exhibited in the side-wings of the building, the charge would be 8 dollars 10 sgr., viz., 5 dollars value and 3 dollars and 10 sgr. space. (For every fraction of a hundred the full per-centage will be reckoned. Every exhibitor will only have to pay the charge on the sum total of the value of all the articles exhibited by him.) 5. As commission-agents for receiving, unpacking and repacking goods, and for acting as representatives of exhibitors, the committee can recommend Messrs. Meyer H. Berliner, Günther, Behrend and Co., Wiesenhütter and Wandel, and D. Witte Nachfolger in Stettin. Every exhibitor is, however, at liberty to apply for this purpose, and for the protection of his interests, to any other firm in this city. 6. Exhibitors must be at the charge of insuring their own goods. The above-mentioned commissioned-agents are willing to undertake the insurance of exhibited articles. The committee cannot be held responsible for loss occasioned by fire, theft, &c., but will take the most ample measures for the security of the articles exhibited. 7. The name and residence of the exhibitors, and, if possible, also the price, must be affixed to each article exhibited. Articles which are not for sale must be marked as such. 8. Exhibitors are at liberty to charge either the committee or any firm of this city with the sale of exhibited articles. 9. Inflammable or easily exploding articles, such as spirits, oils, acids, corrosive salts, will only be admitted in strong and well secured glass bottles. 10. Articles for exhibition will be received by the committee in the Exhibition building from the 1st of April to the 1st of May, 1865. No article can be withdrawn or sent back before the close of the exhibition. 11. Articles of great size or weight, the placing of which will require considerable labour, must be sent before the 16th of April. Bulky articles, which will have to be sunk firmly in the ground, such as machines, must be specially mentioned in the notice sent in by the exhibitor. 12. Exhibitors, who may wish to have their machines worked by steam, must make the necessary arrangements with the committee beforehand. 13. Exhibitors, after obtaining permission from the committee, may appoint assistants to keep in order the articles they exhibit and explain them to visitors; but such assistants will not be allowed to offer such articles for sale. 14. At the close of the exhibition there will be a distribution of prizes, the manner of which will be subsequently fixed and made known. Application has already been made to Government for permission to dispose of the exhibited articles by way of a lottery.

Proceedings of the Society.

FOURTH ORDINARY MEETING.

Wednesday, December 7th, 1864; William P. Andrew, Esq., in the chair.

The following candidates were proposed for election as members of the Society:—

Abel, Charles Denton, 20, Southampton buildings, W.C.
Brinsmead, Henry, 12, Rathbone-place, W.
Sharp, Philip Henry, 18, East-parade, Leeds.
Simonds, Professor James B., Royal Veterinary College, Camden-town, N.W.

Simpson, J. Hawkins, 40, Bedford-place, Russell-square, W.C.

Smart, James Joseph, United Service Club, Pall-mall, S.W., and 3, Lambton-terrace, Westbourne-grove, W.

Sundius, Charles C., 54, Picadilly.

Thompson, Frederick, Urmstone Lodge, Wimbledon-park, S.W.

Varnell, Professor George, Royal Veterinary College, Camden-town, N.W.

Wetherfield, George Manley, 35, Moorgate-street, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Barker, Charles Stuart, 12, Buckingham-street, Adelphi, W.C.

Durham, Makin, Thorne Hall, Thorne, Yorkshire.

Gale, William Joseph, 32, Torrington-square, W.C.

Hale, William, 6, John-street, Adelphi, W.C.

Kirchner, John, Peckham-common, S.

Patridge, William, 48, Newgate-street, E.C.

Pistrucci, Valerio, 28, Camden-street, N.W.

Pite, Frederick Robert, 38, Bloomsbury-square, W.C.

Pittar, Arthur, 4, Kensington Park-gardens, W.

Rowlands, Percy Jones, 24, Notting-hill-terrace, W.; and India Office, Westminster, S.W.

Slater, Robert, 104, Fore-street, E.C.

Smith, William Binns, 3, Upper Bedford-place, Russell-square, W.C.

Thompson, F., South Parade, Wakefield.

Tichborne, Sir Alfred, Bart., Tichborne-park, Hants, and 18, James's-street, Buckingham-gate, S.W.

Todd, William, 24, Wellington-road, St. John's-wood, N.W.

Tozer, Thomas, 55, Dean-street, Soho, W.

Van de Weyer, M. Sylvain (Belgian Minister), 3, Grosvenor-square, W.

Venning, Walter C., 9, Tokenhouse-yard, E.C.

Verschoyle, Colonel H., 23, Chapel-street, Belgrave-square, S.W.

Wilson, George, Cyclops Steel and Iron Works, Sheffield.

Wingate, James Forman, Club-chambers, 15, Regent-street, S.W.

The Paper read was—

THE CONSTRUCTION, TRACTION, RETARDATION, SAFETY, AND POLICE OF RAILWAY TRAINS.

By W. BRIDGES ADAMS.

Wagons and carriages are kept short on railways in order that they may roll round curves. Viewing a train of wagons from a bridge, every wagon will be seen to oscillate from side to side on the rails, following the course of curves and irregularities. Every wagon is drawn by a loose coupling chain, some eighteen inches in length, and the oscillation is so violent that, though goods and coals suffer it, and suffer from it, it would be unendurable by passengers, so the carriages of passenger trains are close coupled together to keep them steady. But in this process the wheels, as constructed, are debarred from following their own courses, and are compelled to slide. The result is a great wear of flanges and of axle-brasses, and a large consumption of coke. Were a train of goods wagons as close coupled as the passenger trains it would be simply impossible to move them. The first thing an engine-driver does, when about to start a goods train, is to back the whole of the wagons one on to another, and then start them one at a time in succession, by snatch after snatch at each chain, which is therefore required to be of enormous strength, in proportion to the resistance of the vehicle to traction by reason of bad structure.

The necessity for close coupling the passenger trains, arises solely from want of the efficient structure to induce free movement to make each carriage tractable instead of resisting—docile and not wilful. The first thing is to attain great length to prevent pitching movement, just as

is the case with vessels on water. But with long vehicles, radial movement of the axles must be attained, as described in a former paper. Radial movement may be obtained by radial axle-boxes to the end wheels very effectually with one pair or two pairs of central wheels to serve as fulcrum on the rails, or with frames of iron fixed to the axle boxes and guided by the traction rod and buffer. The traction rod in such cases will serve in the same mode as a carriage pole on the highway. And swivelling buffer springs will, by coupling chains attached to the iron frames, keep the wheels in the right position while backing the train on curves. Or, if two pairs of wheels, coupled together at each end of the frame, be arranged with a fulcrum or a pivot over one axle and a radial curved lever over the other axle of each pair, they will be self-guided on the rails, and a carriage thirty feet long may roll round a curve of fifty feet radius, and the tender will run, and the less will be the likelihood of getting off the rails, and moreover the less will be the proportionate dead weight of the vehicles to the available load-carrying capacity, if it be rightly constructed. The Americans and other people use long carriages with swivelling trucks supported on a centre pin, which also have eight wheels, and thus radiate the axles imperfectly, though, if the trucks have not length enough, say two feet more than the width of the gauge between each pair of axles, they will not run steady, but will drag their wheels. If the radial system be applied, it would be quite possible to make carriages forty feet long with eight wheels to roll round a curve of 60 to 80 feet radius. A rough model of a vehicle of this description is on the table, and the guiding apparatus of the wheels is not intended for a boggy carrying the load, as in the American carriages, but simply a radial guide, the load of the upper frames being borne by the springs on the axle-boxes, with facility for elastic sliding, or swinging on long vertical shackles.

Some time back a series of medical papers appeared in the *Lancet*, on the subject of the injury experienced by a certain class of patients from railway travelling. The fact was strongly denied by railway authorities, and by many persons in good health who were not authorities. Not long back a railway engineer who had been very doubtful of the injury, informed the writer that he had changed his opinion, for, being out of health, and desiring to travel backwards and forwards to Brighton, he found he could not do it on account of the injury caused by the vibration.

It may be remembered, that when the Brighton line was first opened, numbers of City stock-brokers and merchants took houses at Brighton, and yearly tickets to travel up and down daily, in short, to live at Brighton and transact their business daily in London. The writer has been informed that many ceased the daily practice at the end of the month, and at the end of six months it was found that hardly any could stand it and preserve their health.

Now, what is the reason of this? The carriages were as comfortable and easy, and as well ventilated as an ordinary sitting room when not in motion, and the only difference therefore could be, that the sitting room is stationary, and the carriage moves. But what is the kind of movement? There must be something peculiar in it for physicians to order their nervous patients to travel by road and not by rail. There are two mechanical differences. The road carriage has wheels proper, with independent movement and elastic wooden spokes, and elastic springs, and the wheels roll over a rough but not constantly hard surface. Riding in an omnibus along Cheapside, the rider finds the stone pavement hard and irregular, and the iron pavement much harder though regular, and the iron is the most unpleasant of the two.

The rail carriage has a kind of iron garden rollers for wheels, and they run on a small but hard iron surface. If the carriage be travelling at a mile an hour, as when starting from a station, the movement is scarcely perceptible, but

when at thirty to forty miles an hour, the vibration becomes unpleasant to most, painful to many. In slow movement the wheels can adjust themselves to the rails, and roll or slide easily. In rapid movement they have no time to adjust themselves, but slide as well as roll with incessant jerking. On very sharp curves the movement is sometimes all sliding.

It is this sliding which constitutes the difference. We may illustrate it as follows. Everybody knows that the sound of a violin is induced by rubbing the horse hair string of a bow over the strings of the violin, both being in tension. But the simple horse-hair will not produce the effect. To produce sound the player applies powdered resin to the horse-hair to induce friction, and it is the leaping of these particles over the strings that induces the vibration resulting in "sweet noise." Sometimes, they who love loud laughter better than sweet noise, will, as a practical joke, apply a tallow candle surreptitiously to the horse-hair bow instead of resin, and then the vibration causing the "sweet noise" is stilled. Now the wheels on a rail are in contact of practically rough surfaces, which vibrate and induce torsion of the axle, and thus vibrate and jump, and the result is, not "sweet noise," but very unpleasant noise and jarring, which, if long enough continued, makes a nervous passenger ill, and tends more or less to counteract the peristaltic motion of the intestinal canal. If the rails and tires were rubbed with the tallow candle before alluded to, the vibration would cease, at least till sand enough had accumulated to counteract the effect of the tallow. But the engine-driver would not approve of this plan, as it would lessen the power of haulage.

How, then, is this vibration to be lessened? Firstly, by lessening the hardness of the rail, and rendering it elastic. Secondly, by rendering the wheels elastic. Thirdly, by permitting wheels, or tires, or both, to revolve independently of each other. Fourthly, by radiating the axles so that neither on curves nor straight lines will the wheel flanges be ground against the rails. Fifthly, by efficiently springing the carriages, using a double series of springs, as well known in private carriages. Sixthly, interposing a non-vibrating material, such as india-rubber, between the carriage body and frame. Seventhly, by so constructing the bodies that passengers may stand or sit at pleasure. The blood cannot circulate freely when in a constant sitting position. Sedentary employment is a common source of paralysis.

The next question is that of brakes in absorbing momentum by friction.

When a large mass of material is put in motion it requires at first a much greater amount of power to start it into motion than it does to keep up that motion when speed is attained. The power required to get up the speed is called momentum, and if it be required to stop the momentum it must be absorbed by friction or gravity. If the stopping-places of railways were always on ascents there would be no need for brakes; gravity would supply the place of friction. And if the starting places were always on descents, little surplus power would be needed to produce momentum, as gravitation would furnish it. But momentum has to be absorbed under many varying circumstances,—sudden obstacles to be averted or stopped short of,—stoppage at stations,—and the descent of long inclines; also the ascent of long inclines, in case of couplings breaking or wheels slipping.

In the early times of tramways the Convoy (*convoy*) or brake carriage was used with the train. In the early times of railways brakes were applied to first-class carriages, each worked by a guard, because the first-class were the heaviest. But people who paid first-class fares demurred to this, and sliding brakes were adopted, working on the wheels and axles without attachment to the body, and thus jar was lessened but noise was increased, and so the brakes were transferred to second class, and then the old Convoy—the brake van—was revived, one at the head of the train next the tender, and the other at the tail, and when the train was heavy, one in the middle

But it was to a very small portion of the total weight of the train that the break power was applied, and the guards screwed down the blocks tight, and so skidded the wheels and ground flat places on the tires; and to apply brakes rightly every wheel in the train should have a brake block applied lightly to it, from the engine to the last carriage. The engine should have brakes pressing on both rails and wheels, applied by the driver, through the agency of steam friction, by simply turning a steam-cock, the pressure being divided between the rails and wheels in any convenient proportion. Brakes on every vehicle in the train and on all the wheels would reduce the pressure required on each to a minimum. The system of "continuous brakes," as they are called, is applied to as many vehicles as the power used can reach. But the power used is commonly hand-power, and that is limited.

A new mode has lately been adopted on the North London line of making the momentum destroy itself. On this line of short mileage and many stations, with frequent trains, it would not be possible to work the traffic without the means of rapid stoppage, *i.e.*, the utmost rapidity short of concussion. For this purpose a chain of sufficient strength to draw the whole train is extended beneath and throughout the train. When this chain is drawn straight, the blocks are all on to every wheel, and when the chain sinks into a succession of curves, or bights, by a weight beneath each carriage, the brakes are all off. To draw the chain straight, a pair of heavy cast-iron disc wheels, with a barrel or drum on their axle, are then suspended in slings below the last carriage. The guard, by means of a screw, brings these suspended wheels into close contact with the running wheels of the carriage, and the friction causes the disc wheels to revolve by the momentum and to wind up the continuous chain on the barrel till it is drawn straight, and the brakes are all on, when the disc wheels begin to slip, and the momentum of the train is absorbed by the brakes. In this mode a train of fifty vehicles may be stopped in as short a space as a single vehicle, the right amount of friction being applied to each. This arrangement, however, requires either that the chain be carried through the whole train, and accurately connected with the proper lengths of chain to each carriage, the whole train being pulled close together, or that the break-van at one end and the engine at the other, serve as fixed points to lift the counterbalance weights and draw the chain to a straight line. There is no doubt of this acting well on trains fitted for the purpose, but the writer has not yet seen it applied to mixed and irregularly made up trains.

With regard to the application of brake blocks, there is an advantageous and a disadvantageous method. If applied to the fronts of the wheels, that is in the direction of the pulling engine, they do not chatter on the wheels, whether fast or loosely applied, but when brought into contact with the backs of the wheels they do chatter, till the pressure becomes very strong, so strong indeed as to skid the wheel. The longer the block, *i.e.*, the longer the surface of tire it embraces, the less is the chatter. But it would be far better to arrange the blocks between adjoining wheels, so as to press both rail and wheels, and in this mode there would be no chatter.

But though the continuous brakes before described act so well on continuous trains of vehicles, the action depends wholly on the continuity of the chain, as well as quick movement to apply them. If the chain separates, the brake action ceases at once, and this on a steep gradient might be disadvantageous. It is, therefore, desirable to have the brakes self-acting, if possible, without depending on the human hand, and operating on every vehicle independently of the others—operating also instantaneously when required. The writer was led to study this question, owing to the necessity of enabling the brakes to follow the wheels of radial carriages on curved courses.

To put this in practice brake blocks are suspended from

cross shafts attached to frames resting on the axle-boxes of the wheels. To these blocks long weighted levers are fixed, which cause the blocks to press against the wheels with either a steel yard action or, what is called, an elbow joint, four blocks being used, one to each wheel, with two levers or rods to cross bars. Thus the normal condition of the blocks is, to be pressing on the wheels with a power sufficient for the purpose. The lever ends are attached to the brakes rod by a chain passing between two pulleys on the carriage frame, and as in the process of traction the rod moves lengthlong in the carriage to either end, the chain lifts the levers vertically, the traction force of each vehicle being sufficient for this purpose, and this process operates on every vehicle so fitted, even though ordinary vehicles be interspersed in the train; and in ascending an incline, if a traction coupling parts or breaks, these self-acting brakes will instantly press on the wheels before back movement of the wheels can commence; and in going down hill the brakes will be lifted while the engine is pulling, but will be in action directly the engine is slowed, and they may thus go on pressing and lifting, and so moderating the speed down an incline. It may be objected that the power of the brakes might thus be in excess, and so be a disadvantage, but to equalise this, every vehicle is to be provided with a hand lever, which will enable the driver to put temporarily out of action as many brakes as he may choose, leaving in action the number required for his purpose. The model of the carriage on the table is on a length of rail which may be placed on the level, or at angles of one in 1, in 20, 60, 50, 40, 30, 20, and 10. It will be found that brakes so applied, will retain the vehicle on an incline of one in fifteen, and by snatching the brakes rapidly off and on, starting and stopping may be rapidly performed. In practice the ends of the levers may have sliding balance weights applied, so as to increase or diminish the pressure by the length of the leverage. It must be borne in mind, that the tractive force required to draw the wagon while running, must govern the weight required to be lifted at the brake levers, and in cases where much weight is needed, the mechanism for lifting must be arranged accordingly. When the whole of the wheels are provided with brake-blocks, a comparatively slight pressure on each tire will suffice.

The longer the vehicle the longer may the brake lever be, and the more effective will the vehicles be both for goods and passengers. Coal wagons are made short, for the convenience of getting close to the pit's mouth, but the model on the table, representing a wagon 30 feet in length, will roll round curves of 50 feet radius, and by its great steadiness will carry the coal—a very friable substance, with far less breakage. And a long wagon may be made considerably lighter in proportionate dead weight than two short ones, thus adding to the available load. In these days of competition in coal transit, this is a very important consideration. The self-adjusting brakes described will work equally well, whether the engines be on straight lines or sharp curves, as the levers are arranged to act equally well in either case. And as it is useful occasionally to back the train, for which purpose the brakes must be out of action, this may be accomplished by connecting the traction rod to the buffer rods or buffers by spring agency, so that the thrust of the engine may lift the chains and brake levers in succession, and put the whole out of action, or they may be lifted by hand levers as at present practiced. This class of brakes is especially adapted to steep gradients. There is nothing new in the principle now proposed. It is the safety principle in the cages of mining shafts and on some railways with rope traction.

The last question we have to deal with is what we may call the police of railway trains. This is a question of structure. Trains are subject to catch fire on the roof; passengers may be taken suddenly ill; murders may be taking place, or other violence, but the sound of the train deadens all other sounds, and neither driver nor guard

knows of it. And so there is an outcry for communication between passenger and guard, and guard and driver. And there are propositions for galleries outside the carriages for guards to walk along and catch murderers in the act. It seems to be forgotten that this facility for the guard would also be a facility for the thief or murderer. The practicability of these things is not considered. It is common to talk of the "six-foot" between the two lines of rails as giving ample space for the guard's gymnastics, forgetting that the "six-foot" is reduced to two feet by the overhanging carriages, and that two guards on opposite lines would thus come into collision, and, in American phrase, be "rubbed out."

If the guard is to patrol the train, there is but one way of doing it—through the inside—a passage way through the whole length of the train. Third class would probably not object to this, as they are disposed to be gregarious, and would not object to a guard or policeman additional, but second class might object, and first class assuredly would, on the score that they had paid their money for space and privacy. If it were put to the vote there is little doubt that the vote would be for privacy and a certain amount of risk, rather than gregariousness without risk. It must have been a matter of observation to those witnessing the starting of trains, how first class passengers walk along till they find an empty compartment, and, failing in this, make for one with the fewest occupants. And second class will do the same.

Were the lines single there would be no difficulty, as the carriages might be widened at least to the full extent of the tunnels, but with double lines the "six-foot" is the limit, and sometimes the "six-foot" is only five feet, and even less. With the six feet it would be practicable to have carriages two feet wider, provided only that the passengers would consent to have a wire guard to the windows limiting the protrusion of their hands, like the grating to the windows of a Spanish house. With a

carriage ten feet wide, it would be quite practicable to have a closed passage in the centre, two feet wide, and compartments for four persons each, thus getting rid of the objectionable centre seats. The external doors would be retained, and there would be sliding doors inside opening into the central passage, communicating with end platforms. The second class and third would dispense with the closed passage. Sliding doors, glazed, would prevent the entrance of wind or rain through the central avenues. In this mode it would not be merely on the guard that the passengers would rely for protection, but also on the facility of intercommunication with each other in case of necessity. But if the brakes were all left to the driver, as they should be, the guard would have ample leisure to attend to the police of his train, instead of having his time taken up with the mechanism. Great Western carriages in the first class are divided length long by a partition, with the disadvantage that the compartment next the platform on the near side has to serve as an ante-room to the other. If the carriages were two feet wider this difficulty might be avoided by a central passage. No doubt this might be all very much simplified by making the whole train a series of open saloons, as in America, but public taste must decide this; and even in America they are now beginning the system of private compartments. With the exception of occasional alterations at platforms, it would be quite a practicable thing to widen the whole of the existing carriage bodies, by dividing them in the centre longitudinally and inserting the extra width as ships are occasionally dealt with to lengthen them. And there would be one considerable advantage, that by widening the train the length might be shortened, or a larger number might be carried. It may be objected that a small number—four persons—in one compartment might involve risk in plotted crime; but it would be quite practicable to make one side of the vehicle closed and the other open compartments.

BROAD GAUGE.

NARROW GAUGE.

As a matter of safety in case of collision, the larger carriages are preferable, as they do not mount on each other's backs. As regards the expenditure of momentum by sudden stoppage, which throws passengers violently in each others faces, the safe remedy would be sitting sideways instead of fore and aft; they would be shoulder

to shoulder, and in the safest position; but even in this case it is possible that they would prefer the ordinary position with risk, to side-sitting without risk, at least till they had a practical verification by frontal damage to their persons. The subject is so large that the writer has only dealt with it summarily, but a useful purpose will

have been answered should the paper have given new materials for thinking.

In conclusion, it will be well to help the memory of the reader by a summary of the various propositions contained in the two papers having reference to the amendment of corresponding defects:—

1. Spring tires, for the purpose of preventing blows and friction and lessening the chances of the wheels escaping from the rails, a system thoroughly verified in practice, as quadrupling the durability; illustrated by a woodcut.

2. Systems of elastic permanent railway, supporting the rails by continuous elastic bearing, preventing disintegration of the rails, as verified in practice; illustrated in timber and metal, by woodcuts.

3. Improved system of fish-joints, duplicating the strength, with elastic fit of ribs and bolts; illustrated by a woodcut.

4. Radial axle-boxes, to enable locomotives of great length to pass round any sharp curve without friction on their flanges—in practice; illustrated by a woodcut.

5. Eight-wheel tank engines for sharp curves of 99 feet radius, long verified in practice; elevation and plan illustrated by woodcut.

6. Eight-wheel tank engines, for curves of 99 feet radius, all eight wheels drivers, both on straight lines and curves, by means of super-improved friction-wheels, all capable of retardation by steam brakes, making the whole weight of the engine available for traction or retardation; illustrated by woodcut.

7. System of V flanges to spring-tires working into V grooves of rails, to obtain increased bite for ascending steep inclines, or when starting with heavy trains; illustrated by a woodcut.

8. System of long waggons and carriages on eight wheels, radial axles, and guided by quadrants, with sliding springs, or long swinging shackles, to roll truly round curves of from forty to eighty feet radius, and provided with self-acting brakes, to prevent accidents on steep inclines—economically and easily carrying large loads.

9. Mode of constructing passenger carriages to give free internal circulation to guard, engine-driver, and passengers without interfering with the privacy of first-class passengers; illustrated by woodcut in plan.

These principles and plans are applicable to all gauges, from 7 ft. to 3 ft. 6 in. light lines.

DISCUSSION.

Mr. Dyer said they must all feel much indebted to Mr. Adams for his paper, which contained many valuable practical suggestions, but it did not embrace the popular view of the safety of railway trains by night and by day. The popular view was how the safety of passengers could best be secured, and how the casualties of railway travelling could be diminished. With this in view he would call attention to a few statistics taken from the annual reports of the Board of Trade, which showed that there was great loss of life annually throughout the kingdom from railway casualties. Those statistics had been tabulated only since the year 1861, in which year he found that there were 284 persons killed and 888 injured; in 1862 there were 216 killed and 600 injured; and in 1863 there were 184 killed and 470 injured. These figures showed a large amount of loss of life and injury to persons by railway travelling, making a total for the three years of no less than 2,637. The question in which the public were interested was, could this loss of life and injury to person be reduced? and in this they were more interested than in the mechanical management or construction of a railway. A great number of lives, he believed, might be saved, in cases of collision, by a contrivance (a model of which he had placed on the table), and which, he said, would prevent the upsetting of carriages in case of collision. The loss of life occurred, in a great measure, from the upsetting of carriages on the road. If the carriages could be maintained in their

proper position, the passengers would seldom suffer more than a violent shaking, but immediately a collision occurred the upsetting of the carriages ensued, and loss of life and injury to person, to a great extent, was the result. He considered the present buffer arrangements of trains extremely faulty, inasmuch as their line of action was too low, and gave a leverage, or pressure, which in case of collision lifted the carriage over. He held that there ought to be what he termed a square pressure from end to end of the train, which would enable the carriages to sustain the pressure without being upset; in other words, the carriage could be pressed to the extent of the crushing power before it gave way. The arrangement he suggested consisted of a top and bottom line of buffers, which rendered a train like a continuous carriage in point of resistance to pressure from end to end. If the train could be formed of one continuous carriage, upsetting would be impossible, for, however violent the concussion might be, it would be impossible to upset the carriage. The arrangement of buffers he had suggested would practically make the train into a single carriage. Another question was the frequent loss of life that occurred at station platforms, from persons getting in or out of carriages while in motion. He submitted that all the platforms should be built up to the level of the flooring of the carriages, and that a dangerous space between the platform and the carriages ought not to exist. There was great want of uniformity in the height of railway platforms. He found at Charing-cross station the height of the platform was three feet, while the average height of the flooring of the carriages was about four feet from the rails; consequently, there was an ascent of twelve inches to the carriage. At London-bridge station it was about the same. On the Brighton line, at London-bridge, the platform was only twenty-four inches in height, which gave an ascent of two feet to the carriages, with a space of eighteen inches between the edge of the platform and the carriages, and this he held was dangerous in the extreme. However thoughtless or stupid the public might be, they found that casualties from falling between the edge of the platform and the carriages frequently occurred to the servants of the companies, who might be supposed to know the danger that existed. Mr. Dyer instanced the casualties that had lately occurred from this cause at the Erith Station, when the platforms were crowded with persons returning from the scene of the recent explosion there. He also quoted from the Board of Trade returns other accidents which he said were merely recorded as "passenger killed from own want of caution," &c. He thought the Government ought to instruct the inspectors to inquire into and report the conditions and particulars under which the occurrence took place, but this was not done, except in the more serious cases of accidents. He thought many of the present dangerous arrangements on railways ought not to be allowed to exist, and that it was the duty of the Government, upon the neglect of the companies themselves to do so, to enforce the necessary precautions to ensure the public safety.

Captain Huxley could not see the practicability of the arrangement of buffers that had been just suggested, to carry out which would involve the necessity of building excessively heavy carriages, whereas it was considered essential, both in regard to speed and comfort in travelling, to build them as light as possible. He thought if such a system had come under the notice of Mr. Adams in a way that he could entertain, he would have noticed it in his paper, and given his opinion upon it.

Mr. S. TETLON said the last speaker but one had suggested that railway carriages should be provided with two sets of buffers. He would appeal to gentlemen who had any knowledge of mechanics and of the laws of bodies in motion, whether it was not undisputed that the best point at which to stop a body in motion was not as near as possible to its centre of gravity. In the case of an engine

when the boiler filled with water, and perhaps carrying a tank on the same frame, he submitted that the line of the centre of gravity was not very far from where the buffers were ordinarily placed. At one time the practice obtained of stopping trains on sidings by the very ready but, as it had proved to be, very dangerous method of turning up the ends of the rails. The consequence of this arrangement was, that as the centre of gravity was above the wheels, they, coming in contact with the bent-up iron, had a tendency to be thrown out of their places. The remedy for this was found in putting up an earth bank, against which the buffers impinged, and he could state, from his experience on a very large railway, that since that plan had been adopted the injury to the wheels and axles had been largely diminished. In the plan now suggested what would be the consequence of anything happening to the lower buffers? If the top buffers took the strain, it would push the roof off the carriage, which, he apprehended, would be very inconvenient to the passengers inside it. With regard to the complaint that the platforms were not placed at a uniform convenient height, it must be remembered that railways were not the system of a day. They had gradually grown up, and improvements had succeeded from time to time. In making a new station, such as the Charing Cross, the directors had adopted a higher platform. The Brighton station was built many years ago, but he had no doubt, when it became necessary to make new stations, the directors of that company would follow the example of their neighbours, the South-Eastern. While speaking of the Brighton Railway, he would notice a passage in Mr. Adams's paper, in which he referred to a subject which had excited a great deal of public discussion, viz., the alleged injury to the health of persons constantly travelling by railway. The best answer to that allegation was the fact that, taking the statistics of the Brighton Railway, he found a very large increase from year to year of the class of passengers daily travelling to and from Brighton and intermediate stations as season-ticket holders. The report which was distributed among the shareholders of the South-Eastern Railway Company in the early part of this year contained a table, which showed that while in 1855 the season tickets brought in near £21,000, the amount had gone on increasing year by year, with but one exception, until up to the present year it reached the sum of £34,693. He at one time, as a traveller by railway and road 72 miles, four or five days in a week, fell into the notion that he was being seriously injured by his railway travelling; but he must own now, having continued that injurious practice for upwards of ten years, he had the satisfaction of enjoying much better health than ten years ago. It was fair he should state the result of his own experience. He attributed much of the injury which some passengers suffered to this cause, viz., the short time that persons gave themselves to reach the station which led to their arriving and entering the carriage in a flurried and heated state, unfit for travelling, especially in cold weather. They sat in carriages caused by the carriage moving rapidly through the air, and the caloric of the body was rapidly drawn from the feet, and the proper circulation of the blood interrupted. He turned from this question to the practical matters treated of in the paper. With many of the points suggested by Mr. Adams he entirely agreed. He agreed that a great deal of the mitigated wear and tear of railways and rolling stock was to be attributed to the better form of construction both of the line and the working plant. He had taken a little trouble in this matter since the last meeting, because he held it was of great advantage to discuss these subjects with a number of gentlemen more or less conversant with it, and although they might not agree on all the opinions expressed, they were in all cases the better for exchanging ideas with each other. In the year ending 1855, on a railway on which 2,272

carriages were employed, it was necessary to "turn up" from wear 1,841 pairs of wheels. The actual result was 6726 as the proportion of wheels turned up in 1855, whereas for the year ending July last, the number of vehicles having been materially increased, and increased in size as well, the capacity of the waggons being increased from four and five tons to eight tons, they still found this gratifying fact, that the 6796 in 1855 was reduced in 1864 to 6333; and it was an equally gratifying fact that the quality of the tires—a matter on which Mr. Adams properly laid great stress—had very much improved, especially the Staffordshire tires. He found, on a comparison between the wheels used on two of the large metropolitan lines, that while, in the four years ending 1863, when a great many Low Moor tires were used on the one line, the result was a loss of 60945, on a neighbouring line with Staffordshire tires it was 60990, being a mere difference of 545, and showed very favourably for the Staffordshire iron, which, ten years ago, they hardly dared use, as the quality did not near come up to that of Low Moor. With regard to wheels, the railway he was connected with (South-Eastern), gradually, during the last fourteen years, ceased to have perfectly solid iron wheels; they employed wood placed endways above a plate inserted for the centre of the wheel, and built up to form wooden disc on which the tire was put by hydraulic pressure; they had also done this, and done it very successfully, viz., placed a rim of wood between the iron wheel and the tire. He should state that the former plan was patented by Mr. Mansell, the carriage superintendent of the South-Eastern. As the tires had become worn, they had cut out of hard wood a segment of an inch or inch and a half, and placed them between the inside of the tire and the iron forming the old wheel. These plans had answered so well, that whilst during the last severe winter, the tires of 150 pairs of wheels, some on iron, had elongated, where this hard wood had been placed between the tire and the wood of the disc, there was no wheel amiss, a very important matter in times of severe weather. The elongation of tires in winter time had been a very vexed question, but he thought a little consideration would bring them to this conclusion. The road in severe weather, especially if the frost had been preceded by wet, was in its most rigid state. Then the inner portion of the wheel, when of iron, was in effect the same as if the tire was placed between rollers, and consequently it elongated the tire. With reference to the model of an elastic road shown by Mr. Adams, he imagined that was another move in the right direction, and that plan had been adopted on one of the lines running from Manchester. The chairs were placed between the wheels, as in that model, and he stated this on the authority of Mr. Ashcroft.

Mr. ADAMS—If the plan was good why did not Mr. Ashcroft employ it on his own lines?

Mr. TEULON said it must be well known to Mr. Adams that a framed longitudinal road was formerly employed on the viaduct portion of the Brighton line, and was one of the best parts of the line; but owing to the great number of trains, when it was taken up it was impossible to put down another road like it. It was, however, in use some ten or twelve years with success. With regard to the spring tire wheels which Mr. Adams had shown, he (Mr. Teulon) thought that in ascending inclines difficulty would be found, inasmuch as the wheels would slip in the tire for want of sufficient friction.

Mr. ADAMS—The objection could only apply to the driving wheels of engines; as regarded other wheels facility of slip was a positive advantage. As regarded driving wheels positive experiment, which was worth more than any theory, had demonstrated that even when the tires, as stated in the paper, were so loose that they could be moved round by hand (with the weight lifted), they drew their load perfectly well. Mr. Adams would go further, and say that loose tires, even without springs, would act in the same way, although of course disadvant-

ageously for want of the elastic interception of blows, and the equalising movement of the tire on its basis of contact with the rail.

Mr. TEULON added that Mr. Adams had stated very correctly that all changes with regard to railway plant, especially with heavy and powerful bodies like engines, must be made with great caution, and therefore he was content to wait on this point till he saw more of the results. In conclusion he would say a word on the subject of the fish-joint. He saw by Mr. Adams's previous paper that he did not call in question the fish-joint at present in use, but he said he had got something better. He (Mr. Teulon) thought the public was very much indebted to Mr. Adams for his original fish-joint, and he hoped that gentleman had reaped some of the benefits of that invention. [Mr. ADAMS—Not a sixpence.] It was a good joint if the fish were properly made, and was one of the best things that had been introduced on railways for a long time. He would not say Mr. Adams might not have improved upon it, but the original joint had been a great advantage to all railways that used it.

Mr. ADAMS, in reply to the observations that had been made, said the model of the suggested application of double sets of buffers was simply a supplementary mode of attaining what he himself had advocated in the paper, viz., the long carriage. In the early days of railways a single buffer was used in the centre, but it was abandoned for the two side buffers. He did not agree with Mr. Teulon that it was a bad plan to put buffers in the position in which they were shown in the model, because it was notorious that short carriages would ride upon one another's backs. No sooner did they come into collision than, with four tons of buffer springs pressing, the first thing they did was to mount upwards on each other's backs, as they could not move downwards or sideways. That was well known from experience. He did not think that two sets of buffer springs, one above and one below, were desirable, but he thought it would be an advantage to apply cushioned blocks to the upper corners of the body, flush with the buffer heads when drawn home, to lessen the risk of the tilting upwards. With regard to the question of health, he could not fight against statistics; but in his paper he had alluded to what he understood was the fact, not that season tickets originally taken by gentlemen wishing to travel morning and evening to and from Brighton had been discontinued, but that very few persons could keep up the daily practice; and though the season tickets might have increased in amount *non constat* that all their owners travelled with them morning and night.

Mr. TEULON said his inquiry had been especially directed to that point, and there were persons travelling backwards and forwards continuously.

Mr. ADAMS was glad to find they had such quality of muscle in England, but one engineer had told him the practice did not suit him. And it was notorious that the faculty discouraged their delicate patients from the use of the railway. With regard to the wheels which Mr. Teulon had alluded to, before that gentleman had gone far in his remarks on that subject, he (Mr. Adams) was prepared with a reason why the wheels on the South Eastern Railways had lasted longer. It was solely due to the fact that they were wheels with solid wooden discs, which to a certain extent rendered the wheels true circles, and also removed the inner anvil from the tires. They could not hammer the tire on the surface of the wood as they could on an iron surface, just as the shoemaker in hammering his sole leather could not do it on his thigh as he could on a solid lapstone. As to wooden wheels, nobody knew more about them than he did. He was at one time a manufacturer of carriages and engines, and had turned out a great many of them. There came to him an order from the South Eastern Company for a number of very long carriages. Those carriages were notoriously the steadiest carriages that ever ran, but they did not answer in one respect, as

he had not in them a radial movement of the axles, and the flanges cut against the rails. When the order for them was given, it was specified that the wheels were to be constructed on Mr. Mansell's patent. That patent was not for wood wheels, but consisted in applying, in an ingenious manner, a pair of angle-iron rings which keyed laterally into the grooves of the tire, and held to the wheel by cross-bolts through the wood, piercing through the head of the tire. In making a wheel the worst thing they could do was to make a hole through the tire, because it deprived it of a portion of its strength—probably one third. Another thing was, when the tire got loose on the wheel it indicated danger, which arose in this way—Where the tire was stretched by the process of rolling over the rails, the wheel being held down in eight points, it could not stretch where it was held, but became polygonal in stretching out between them, and the wheel in other parts became a sledge hammer, and in frosty weather the rivets got broken out. The original wheels of Mr. Mansell were composed not of a disc of wood, but of a series of screw spokes, the outside secured in the felly, and the inside in the nave of the wheel. On looking at that plan, he declined to make such wheels. He was asked how he would do it. He replied, make them solid discs with a series of radial timbers. He was told that was the patent of another superintendent, but he doubted the fact, as it had been done by Mr. Dircks many years before. He (Mr. Adams) had machinery made to cut the timber for those wheels, and they were the first that were thus made for the South Eastern line. He was then putting on Park-gate tires, said to be a brittle iron, but he found it perfectly hard, and of good quality. While these wheels were in course of manufacture, an accident occurred on the Midland Railway by the breaking of a tire, which cut through the bottom of the carriage, and nearly killed the railway king, Mr. Hudson. Inquiry was immediately made of the officials whose tire it was that had broken? and on being informed it was Park-gate, he issued orders that no more of those tires should be used on any railway of which he had the command. Upon this he (Mr. Adams) was asked if he intended continuing to use the Park-gate tires? He replied, he did. He was told they would break, to which he replied he was putting them on the wooden discs by pressure, and by no subsequent pressure could there be sufficient tension put upon them to break them. He believed these wheels had never broken a tire. The greater duration of the South-Eastern wheels was, therefore, due to the action of the wood, which prevented the rails and chairs becoming anvils for the tires to act upon. In America Mr. Griggs had put his engine-tires on with wood between the tire and the wheel, and by that means, no doubt, had increased the duration of the tire very considerably; but in the case of a wooden wheel, if the tire got loose by any chance, and began to move round, it would soon grind the wood wheel away. With regard to his plan of laying the rails elastically, a few years ago, Mr. Chubb, a director of the North London Railway, complained to him of the destruction of the rails on that line. His reply to that gentleman was, that they did not lay them right, and he offered to give him a plan if he liked to use it. He gave him this plan and it was determined to use it. A few lengths were laid down on the North London line with the ordinary rails and in other places. The rails did not touch the longitudinal timbers, and were supported, not by chairs, but by brackets. They had been down three years, but they exhibited no signs of destruction on the top, as was the ordinary result of the anvil action of the chairs and hard ballast. At the time he read a paper on this subject before the Institution of Civil Engineers, it was stated that that kind of road had been adopted before, but he was unable to find any trace of it, in any book or publication, or transactions. It was asserted that it had been done by Mr. Buck, who he admitted was a perfect judge of a good line. He inquired where it had been laid, and

was informed on a viaduct; but it had not been renewed on the same plan, and no one knew anything about it except those who laid it down. Mr. Teulon said he got his information from Mr. Ashcroft. Now the latter gentleman was a member of the Permanent Way Company, which had become possessed of his (Mr. Adams's) fish-joint. It was a company got together to secure all that was good in patents of every kind appertaining to the permanent way of railways. Mr. Ashcroft was, he believed, still a member of that company, and had a patent for a permanent way of his own, on which many heavy chairs were used, and it was only natural he should give the preference to his own plan. But that fact precluded either him or Mr. Teulon, who acted under his advice, from being unprejudiced judges of any clashing plan. He gathered from Mr. Teulon's remarks, that he wished, under his information from Mr. Ashcroft, to make it appear that he (Mr. Adams) was not original in his elastic system. But the truth he believed was, that Mr. Buck, a man in his own right, and not a copier, did use on a viaduct a system of interspersing his chairs between the rigid supports of the frames, to save the viaduct from damage. But in what was called the permanent way of railways, no such system was ever used. He (Mr. Adams) had embodied a known principle of nature to counteract the evil of hard ballast, more than once alluded to by the late Robert Stephenson, in discourses at the Institution of Civil Engineers. Mr. Buck was a man of clear perception, and he also took patents, but never took a patent for this elastic system, or ever mentioned it before scientific bodies. With regard to the framed longitudinal road on the Brighton line, alluded to by Mr. Teulon, it was laid with continuous bearing bridge rails on longitudinal timbers. The bridge rails deflected under the wheels and sunk into the timber to an inch or more in depth. An engineer of the S. Eastern line, when he first saw a rail removed asked, very innocently, "Why do you groove your rails into the sleepers?" thinking it had been done from the outset. This line was always harsh and rigid, and not one to be recommended. He (Mr. Adams) had devised a general system, and applied it equally to timber and metal sleepers, to prevent blows and breakage. With regard to the fish-joint, when the original joint was first produced, he (Mr. Adams) had not intended it to be used in the way it was now used. It was produced as a parallel support to the rail ends between two chairs, six inches apart; afterwards, for the sake of cheapness, it was proposed to bolt it. The form which was good in the chairs as a parallel fish was not proper as now used. It was notorious that the fishes bent at the joint, and as they had only three inches depth between the two upper tables of the rails, they were not deep enough to supply an equivalent in strength to the depth of the rails. Another thing was, they were parallel, and, being parallel, they added more strength than was wanted at the end of the fish to the rail, and that caused a blow, and less strength than was wanted at the joint of the rail, and that caused another blow. He (Mr. Adams) had now devised another form of fish. It so happened that the Permanent Way Company had made what they called, an improvement in fishes, and probably a dozen patents for improved fishes had since been obtained, and it was certainly competent for him, who originated the fish, to make improvements upon it. He did not think the public were thereby endamaged, nor did he think either the public or Mr. Teulon would desire to dispute his right to make a profit of his further improvements, even though the first fish had yielded a miraculous draught of coin to its possessors. He had seen few fishes of a worse form than the last pattern on the South Eastern line.

Mr. DAVIS wished to state that he had had some experience of the engine alluded to in the paper, as having been constructed for the St. Helen's railway, and was present, in company with the most eminent engineers and locomotive manufacturers, at the trials made with it on the North London line. When running on a straight line, at a speed of 68 or 70 miles an hour, he was very much struck

with the beautiful motion of the axle-boxes. Running at that high speed, an inequality of the rails would sometimes cause the engine to give a jump on one side, but it immediately righted itself in the most beautiful manner. After the experiments he examined the wheels, and he noticed that the flanges were not abraded, but the tire had formed a groove corresponding with the surface of the rail. Although the papers of Mr. Adams were very comprehensive, there was one subject which had not been touched on. It had been stated in the discussion that where one carriage ran off the line, if the couplings did not break, the other part of the train would be dragged to destruction. He had had brought under his notice a very clever invention, by which the couplings of the carriages were so arranged that, taking into account the sharpest curves, the couplings, by a clever mechanical arrangement, immediately disconnected the carriage from the other part of the train, and saved it from destruction. He thought this contrivance should be more prominently brought before the notice of railway managers than it had yet been.

Mr. ADAMS said that on the St. Helen's engine they were all spring tires.

Mr. DAVIS replied in the affirmative, and added that he was much delighted with the sensible improvement in the non-vibration of the engine.

The CHAIRMAN had great pleasure in proposing a vote of thanks to Mr. Adams for his excellent paper. It was only to be expected that, looking at the scope of subjects embraced in this and the previous paper, difference of opinion on some points would arise. An objection had been taken this evening that Mr. Adams had not cared sufficiently for the public safety in railway travelling. Now if he understood aright the suggestions of Mr. Adams, they went very much in that direction, not only by diminishing the wear and tear of railways, but they had much to do with regard to the safety of the trains. He would not detain the meeting by entering into the fish controversy, but it illustrated the old adage that "there are as good fish in the sea as had come out of it." The first fish, and a good one, had been produced by Mr. Adams, and he was now ready to produce a better. Mention had been made of the safety of railway carriages, arising from their length and breadth, but no mention had been made of carriages having upper stories. For several years past that description of carriage had been worked on the Bombay and Baroda line, with much success and much safety, and so agreeable had it been found by the passengers, particularly the natives of India, that the company with which he was connected (Scinde, Punjab, and Delhi) had adopted the plan, and used it for a considerable period. He would state as a question of railway management, that they could convey in one of those carriages very nearly as many passengers as they could in three ordinary carriages. Hitherto no accident had occurred, and the natives infinitely preferred the upper story. As one for many years connected with railways, he would express how gratifying it had been to him to have been present on this occasion, for he felt he had received a great deal of instruction, and it was very agreeable to him to hear that as they gained experience in railway construction the dangers of that mode of travelling were materially diminished.

The vote of thanks having been passed,

Mr. ADAMS acknowledged the compliment paid to him, and remarked that one element of safety in reference to those carriages on the Indian lines consisted in the gauge of 5 ft. 6 in., which allowed a wider base for the wheels of the carriages. With that gauge they could do a great deal more than with the national gauge of this country.

OPERATIVE COACHMAKERS' INDUSTRIAL EXHIBITION.

The following circular has just been issued by the committee:—

"The committee of the above have the pleasure to in-

form you that the proposed exhibition has met with more sympathy, support, and encouragement than they could have reasonably anticipated for so novel a venture in the coachmaking trade: not only has the Society for the Encouragement of Arts, Manufactures, and Commerce, consented to bestow its patronage on the undertaking, but the committee have secured the support and assistance of the Worshipful Company of Coach and Coach Harness Makers of the City of London. In reply to the memorial so numerously signed by all the principal London Coachmakers, and many of the most intelligent and enterprising of the operatives, the company have in the most handsome manner placed their Corporate Hall at the disposal of the committee for the purposes of the exhibition.

"The committee consider themselves most fortunate in having thus obtained the support and co-operation of two corporate bodies that have existed for so many years, and they anticipate the most favourable results from this connection of the City company, and trust that the advantages may be many and mutual.

"Messrs. Boulnois have kindly granted to the Committee the use of a most eligible committee-room at the Carriage Bazaar, King-street, comfortably warmed and lighted; this has been another great advantage, besides curtailing the expenses in a material manner.

"Although the sums receivable for admission will doubtless cover much of the expense, yet in so new and technical an Exhibition the Committee cannot look forward to any large sum from the general public.

"It is anticipated that by bringing together many objects of skill, ingenuity, industry, and curiosity, many and various advantages will be offered to the operatives, the coachmakers, and the general public, besides stimulating invention and skill. If the London coachmakers and friends and patrons of coachmaking will support the undertaking with subscriptions, the success will be rendered almost certain, and such success would tend to raise the trade of coachmaking to that position which it ought to occupy amongst the trades of the country, on account of the ingenuity and large capital, and very varied skill necessary to carry it on with success.

"A duly authorised person will, in a few days, call upon you, in the hope that the subject will receive your favourable consideration.

"Several sums have been already offered as Special Prizes:—

"Mr. G. N. Hooper offers three guineas for the best drawing of a town barouche on under and C springs—scale 1-inch to the foot. Open to foremen, carriage operatives, and apprentices.

"Also two guineas for the best drawing or model of a light hospital carriage to convey the sick poor. Open to all comers.

"Mr. G. A. Thrupp offers two guineas for the best stuffed and quilted carriage cushion in morocco leather. Open to coach trimmers only.

"Also two guineas for the best drawing in pencil upon paper (half the full size), of an under fore-carriage for elliptic springs, of usual or original design. Open to apprentices and improvers.

"It is suggested that such a special prize list offers an excellent opportunity to any individual or firm to stimulate skill, ingenuity, or invention in some particular channel that they may consider most useful; and directing the attention of the operatives to objects that would repay the time and thought bestowed on a subject, and which frequently unless guided has a tendency to be bestowed on matters that have no practical utility, though ingenious and clever.

"If you are the possessor of any curious models or carriage drawings, &c., that would be of interest in this Exhibition, the committee solicit your kind loan of the same during the period from January 21st to February 15th, 1865. The utmost care would be taken of them."

ADULT EDUCATION.

A conference took place on Nov. 22 at the rooms of the Society of Arts, John-street, Adelphi, in connexion with the Metropolitan Association for Promoting the Education of Adults, on the subject of the organization and management of night schools; Sir THOMAS PHILLIPS presided, and briefly explained the object of the meeting.

The Rev. HENRY WHITE, M.A., chaplain of the Savoy, delivered an address, prefacing it by stating that he had been largely mixed up in the conduct of night schools for several years, and that he had seen reason to change some of the opinions he had advanced four or five years ago. He proposed to confine his paper to the following subjects:—"The need for night schools specially suited to boys of an age stretching from 13 to 18. The desirableness of changing the name of night schools to the more attractive name of youths' club or institute. The best method of raising or adapting buildings for the use of evening schools. The advantage of reading and recreation rooms in connexion with the evening schools. The classes most needed to be formed for a boys' evening school. Are paid or voluntary teachers most to be desired and encouraged? How can night schools be maintained on self-supporting principles?" He then dilated at some length on providing night schools suited to boys between the ages stated, quoting a paper of Mr. Hollingshead, published last year in the *Daily News*, pointing out the difficulties under which "hobbledehoy's" labour for want of congenial and profitable occupation in their leisure hours, and deducing from these premises the value of providing night schools, but under some other name, in which not only should educational facilities, but opportunities for amusement and social enjoyment be provided. He suggested that youths' club or institutes would be the more appropriate name for the institutions he contemplated, as expressing more accurately and attractively their proposed objects. The class he proposed to benefit was the sons of working men after they left school. He recommended that the National School-rooms should be used for these clubs or institutes, urging that it would be difficult to obtain the means of providing other buildings for the purpose, and that were it otherwise, the money spent in building or in rent might be much better employed. Besides, he believed that in the National Schools they would better secure the class of boys they desired to influence, and that this use of these schools would be advantageous in the education given in day schools. Again, there clustered round the National School a variety of institutes, savings bank, &c., of which the youths would avail themselves. He pointed out the various other advantages he anticipated from the adoption of this suggestion, as the obtaining of the government grant, the assistance of the National schoolmaster, and the sympathy of the parishioners. He considered paid teachers would be necessary for these night schools in addition to the voluntary educational and other help which would doubtless be afforded. He attached great importance to the assistance of ladies as a means of refining the habits, thoughts, and manners of the boys. He recommended compulsory attendance to at least three classes weekly, and that there should be a discretionary power of discipline. There should be a reading-room, a place for draughts, chess, and similar games, and opportunities, within certain limits, for education and social intercourse. This requirement might perhaps be met by devoting one hour previous to and one hour after study for amusement. And in the summer months there should be provision for cricket, boating, and gymnastics. He held it to be a vital point that those institutes should be self-supporting, and in this respect he admitted that he had committed an error in the institution he founded some years ago at the Lowther Arcade. The rate of payment must vary according to circumstances. 4d. to 6d. weekly had been found to meet the needs of London boys, but perhaps in the country 3d. or 4d. would be more suitable. He considered that there should be an

entrance fee of double the weekly payment, as an inducement to continue attendance, but there should be no extra payments for lectures, classes, or entertainments. He recommended that there should be periodical examinations and distributions of prizes. All would, he thought, admit that some religious guidance was requisite for the members of these institutes. He would not exclude dissenters, but it was in vain to expect that a youths' institute could succeed upon the principle of embracing all denominations. He had seen many promising institutions come to grief from the impossibility of getting managers of different religious views to act together. If the dissenters desired such institutes they should provide them for themselves, but their starting point must be the church of England.

Mr. HARRY CHESTER followed, explaining the advantages of Examinations as carried on by the Metropolitan Association, and showing the necessity of affording to the sons of the working classes the means of pursuing their education after the period at which they usually left the elementary schools. He described the nature and form of the Examinations of the Association, adding that none were examined under 16 years of age, and that the Examination papers were sent round to the localities where the pupils resided. He altogether dissented from the opinions of the last speaker as to the religious question, considering it of the greatest importance that members of the different religious bodies should be brought to act together in the work of education, and he was happy to say that he knew of several Institutions in which members of the different religious bodies laboured harmoniously together, and with the best results. He could state that the working classes were by no means indifferent to the value of continuing their education after leaving the elementary schools—on the contrary, there was a strong and even an enthusiastic desire for it. The Metropolitan Association did not confine itself to youths of between 13 and 18, to which Mr. White's paper was limited, but extended its facilities and its system of Examination to adults generally; and they actually found people coming up of the age of 45 or 50, although the majority were between 16 and 22 or 23. As to using the national schools for the purposes of these Institutes, he thought much was to be said on both sides, and pointed out numerous objections to the proposal.

Mr. TABBUM, hon. secretary of the Islington Youths' Institution, which had been alluded to by Mr. White in the way of illustration, offered some remarks explanatory of the system there pursued and the beneficial results.

A discussion followed in which the Rev. B. F. Smith, diocesan inspector of schools for the archdiocese of Canterbury; the Rev. Mr. Whittington, principal of the City of London College; Mr. Pearsall, secretary of the London Mechanics' Institution; Mr. Ford; the Rev. W. Baird, of Clare-market; Mr. Baker, of the Bayswater Institute; the Rev. A. B. Suter, Mr. Whittingham, Mr. Solly, Mr. Stock, and Mr. Currie took part.

The Rev. Mr. WHITE replied briefly, and a vote of thanks was accorded to him and the Chairman.

Fine Arts.

PUBLIC WORKS OF ART IN PARIS.—Architects, sculptors, and painters, have not for a long time enjoyed so much patronage as at the present moment in Paris. In all quarters of the city new buildings are rising; here a church, there an opera house, or a barrack, presently an hospital or a post office, and old edifices are being renovated and beautified. An important work has just been entrusted to a well-known painter, M. Robert Fleury,

namely, the execution of four large works for the decoration of the great hall of the new Tribunal of Commerce, which has been recently erected, facing the Palais de Justice, and between it and Notre-Dame. The subjects selected are:—The Installation in 1563 of the *Juges Consuls*, or commercial arbitrators; the presentation, in 1673, to Louis XIV., of the Ordinance of Commerce; the promulgation of the Code of Commerce in 1807, by Napoleon I.; and the inauguration of the present tribunal. The work will occupy the artist about three years. The river façade has recently been completed; it is ornamented with four colossal figures representing Law, Firmness, Justice, and Prudence, executed in Caen stone, by the sculptors Elias Robert, Endes, Hippolyte Chevalier, and Jules Salinon, and with cariatides by A. Carrier. In niches on the grand staircase are to be placed four grand allegorical groups, representing Maritime and Land Commerce, and Industrial and Mechanical Art, by Cabot, Michel Pascal, Maindron, and Chapu. A copy of the portrait of the Emperor, by the late painter, Flandrin, and which was exhibited in London in 1862, has been ordered of M. Ronjat for the great hall or audience chamber. The works connected with the courts of law and the prefecture of police have been pursued with great activity. One wing of the latter is completed as far as regards the outer walls; the new Court of Cassation is roofed in, and the ornamentation of the new façade of the Palais de Justice itself will be completed very shortly. The doors of the front, three in number, lead into the great vestibule, or, as it is called in Paris, the *Salle des Pas-Perdus*, a noble vaulted apartment. Within the latter is a very bold double staircase leading to the Courts of Assize. Another building, just commenced, will unite the old and new portions of the palace. The whole promises to be the most important work of the kind, after the Louvre and the Tuileries, executed in Paris for many years. Painters and sculptors are beginning to think of the annual exhibition, and are pushing on the works they have in hand rapidly; the decoration of four chapels in the church of Clignancourt, commanded by the authorities of the city of Messieurs Barrias, Emile Lafon, Michel Dumas, and Romain-Cazes, are approaching completion. The pavilion and wing of the Tuileries, which have been rebuilt, are now being crowned with elaborate ornaments in hammered lead, and the ornamental work of that part which abuts on the quay is being commenced. On the other hand, the whole of that portion of the great gallery which was built in the reign of Louis XIV. is demolished, and its reconstruction, in harmony with the work of Henry IV., will be commenced forthwith.

PUBLIC STATUES IN FRANCE.—A grand monument is about to be erected to the Chevalier Bayard, the knight who gave François VI. his spurs on the battle-field, on the ruins of what was once his castle.—A monument to the memory of the painter, Hippolyte Flandrin, is to be raised in the old church of Saint Germain des Prés, where his best works are to be seen. These two memorials are to be raised by subscription, and the Emperor has headed each list with a donation of a thousand francs.—A statue of the naturalist, Daubenton, has just been uncovered in the Jardin d'Acclimatation in the Bois de Boulogne. Daubenton was a member of the Senate and of the Institute, professor of natural history, and member of nearly all the great scientific societies of Europe. France owes to him the introduction of the merino sheep. His remains are buried, according to his own desire, near the fine cedar of Lebanon, at the foot of the mound in the Jardin des Plantes, and a truncated column marks the spot.

LYONS ART EXHIBITION.—The exhibition of the Society of Friends of Art of the city of Lyons is announced to open on the 7th of January. The purchases at the last exhibition of the society amounted to about £2,300. The reception of works closes with the current month.

EXHIBITION OF OLD FAIENCES.—The town of Rennes opened an exhibition of French faiences on the 25th ult., which is to close on the 10th inst. The object, as expressed by the committee, is to institute a comparison between the various fabrics of the kind in France, and to elucidate the birth, apogee, and decline of this industry, to revive which great endeavours are now being made. An appeal was made to all persons who possessed specimens of the pottery of the 16th, 17th, and 19th centuries, and particularly for such pieces as bear signatures and dates, whether objects of ornament or utility. The undertaking is under the presidency of Dr. Aussant, who is an authority on French ceramic art.

ORIGINAL DESIGNS FOR PUBLIC WORKS.—It was the practice formerly of artists to give up to the authorities of the city of Paris the sketches of works executed, but from 1830 to 1863 this was not the case, and consequently the designs for the greater part of the Hôtel de Ville, and of other public buildings, by Ingres, Delacroix, Flandrin, Coignet, and other eminent artists, have been distributed. The municipality at present makes it an express stipulation that such designs and sketches shall become the property of the city, and intends to collect them together in a gallery. Such a collection will doubtless be highly interesting, but in some cases a great loss to the artist; the original designs by Eugène Delacroix sold for immense sums the other day, when his works were distributed by auction. The decision, however, may apply only to the finished drawings, and not to the rough drafts which are so much sought for by amateurs.

NEW THEATRE AT PALERMO.—The authorities at Palermo have announced a competition for a new theatre, to contain three thousand spectators, and for which the sum of £100,000 has been voted. Five prizes are offered, varying in amounts from 25,000frs. to 2,000frs., and all the world is invited to compete.

FINE ARTS IN FRANCE.—Arrangements are being made in Paris for an exhibition of pictures exclusively of the German school. The Emperor has granted the sum of 15,000 francs (£600) for the completion of the exterior decorations of the museum at Orleans, which is installed in the house known as that of Diana of Poitiers.

MONUMENT OF FRANÇOIS I. AT COGNAC.—This colossal group, in bronze, which M. Etex has had in hand for five years, was uncovered on the last day of October, in the presence of an immense concourse of people. The monarch to whom the monument is raised was born in the town of Cognac. The principal group represents Francis as conqueror at Marignan, at the moment when his horse is wounded by one of the Castillans, or mercenaries, whose sole duty was to disable the horses of knights and men in armour and bring the latter to the ground. The pedestal is composed of four immense blocks of marble, brought from Italy for the purpose; on its principal face, sculptured in alto-relievo, are two genii, supporting the arms of the hero, and resting on a battle-axe and a cassetête; on another face are the arms of the town of Cognac, and right and left of these are male and female figures occupied in gathering grapes for the vintage. The other sides are occupied by a bassi reliev in eight compartments, the subject being:—Louise of Savoie lying on the historic stone of the park, after having given birth to François, whom she called her Cæsar; François knighted by the Chevalier Bayard; the King sleeping on a gun carriage, his Italian trumpeter sounding the *réveil*; François in court dress giving audience and aid to artists and *savans* in the Palace of Fontainebleau, Leonardo de Vinci in the foreground; the field of the cloth of gold; Marguerite, his sister, visiting François when prisoner at Madrid; the citizens of Cognac refusing the ransom of the King to the envoy of Charles V., the Comte de Lannoy; François showing the tombs of Dagobert and Queen Nantchilde, in the church of Saint-Denis, to Charles V.

STATUE OF CLAUDE LORRAINE IN BAVARIA.—The young King of Bavaria has just had erected a monument

in honour of the famous painter in the little chateau of Harlschug, where he resided for some years.

Manufactures.

FLOATING STOREHOUSES FOR INFLAMMABLE SUBSTANCES.—The accidents which have recently occurred with gunpowder and petroleum oils have induced the French authorities to establish a new system of storing such dangerous commodities. The method adopted is the construction of iron lighters, divided into proof compartments, and the isolation of these in rivers or basins. Two of these new magazines have just been launched at Saint-Ouen, between Paris and Saint-Denis, where an extensive commercial dock and entrepot have been established, and three more are under construction; each contains one hundred divisions, and each of the latter measures 25 tons in contents. The vessels are entirely of iron, but are covered on the deck and down to the line of flotation with wood, as a protection against changes of temperature. They are moored in the middle of a large basin, and can be swung round to the quay when required for loading or unloading.

NEW MORDANT.—A new mordant, for aniline and other dyes, is said to have been discovered; it consists of acetate of aluminium and arsenite of soda, and the discoverer, M. Schultz, believes that it is destined to replace albumen, gluten, tannin, and other matters now employed for the same purpose. He mixes, at the ordinary temperature, four grammes of the aniline violet of commerce, in powder, with a quarter of a litre of acetate of alumina, and twenty grammes of arsenite of soda, thickening it with starch boiled in water—the quantity of starch to be diminished in proportion to the darkness of the colour to be fixed. In the case of prints, it is recommended to mix the arsenite of soda and the acetate of alumina with the colouring matter, and to steam the fabric or yarns over the mixture. For dyeing, it is said to be better to treat the tissue, or yarns, in the first place, with a mixture of the two salts, and afterwards to dip them in the colour vat in the ordinary way. Salts or compounds of tin, combined with alumina, may be used instead of arsenical acid.

DISCOVERIES IN ELECTRO-PLATING.—M. Weil, a French chemist, announces a new method of depositing metals. The baths he employs consist of metallic salts or oxides in alkaline solutions by means of tartaric acid, glycerine, albumen, or other substances, which prevent the precipitation of the oxide by the fixed alkali, in some cases with and in others without the aid of zinc or lead, and at various temperatures according to circumstances. He claims also to be able, by like means, to give variety of colour to articles covered with copper by his process. M. Weil says that the most important application of his discovery is the deposit of copper and the bronzing of iron (cast as well as wrought) and steel, without the preparatory dressings with conducting substances, which are necessary in proceeding according to the ordinary methods before the object is placed in the bath and submitted to galvanic action. This, if it bear the test of practice, is a very important fact. Iron and steel thus coated with copper may, says M. Weil, be afterwards silvered or nickelised by his process.

NEW BLASTING POWDER.—M. Nabel proposes to make use of pyroglycerine (explosive glycerine) to increase the force of gunpowder for blasting purposes. It is said that experiments, made in the presence of a commission, prove that such a mixture is three times as effective as gunpowder alone. The cartridges made use of were of zinc; these were filled with gunpowder, and as much pyroglycerine was added as the powder would absorb. The detonation is said to be much less than that of gunpowder alone, but, on the other hand, the danger from accidental explosion is much greater, and, moreover, pyroglycerine is a powerful poison.

IRON PRODUCTION IN NORTH AMERICA.—The value of the iron made in the States was estimated by the census returns at 20 million dollars in 1850, and 28½ million dollars in 1860, being an increase of 24 per cent. in the ten years.

COAL PRODUCTION IN THE UNITED STATES.—The coal production in the States in 1860 was 15½ million tons, of which 9½ millions was anthracite. Of bituminous coal Pennsylvania produced 45·8 per cent. of the quantity, and 31 per cent. of the value of the whole; of all kinds of coal, 15·8 per cent. of the whole.

CALIFORNIA SILK.—The soil and climate of California are admirably adapted to the growth of the mulberry-tree in all its desirable varieties, to the breeding and feeding of the silkworm, and to the production of silk, more so than almost any European country, owing to the fertility of the soil and dryness of the climate, giving a peculiarly rich and nutritive character to the leaves of the mulberry tree, which imparts a higher, finer, and more delicate quality to the silk produced from them. Certificates from the highest authorities in Europe show that the California silk, after being tested, carefully analysed, and compared with European silk, proves to be of the very best quality.

IMPERIAL TOKAY.—The village of Tokay, which gives its name to the wine, is situated in Hungary, on the top of a hill, at the confluence of the rivers Rodrog and Theiss. The vineyards occupy a space of ten square miles. The earth is of yellow chalk, mixed with large pebbles. The wine is white, and the vintage is commenced as late in the year as possible, but generally at the end of October. There are four different kinds of Tokay. The first is made by placing the sound grapes in a wooden vat with a double bottom, the one on which the grapes rest being pierced with small holes. The vat is filled with grapes, and covered with boards. After a few hours, the grapes become heated to 80° Fahrenheit, and fermentation begins. This destroys the tartaric acid, and the weight of the grapes forces the juice through the holes at the bottom. The grapes are then trodden by foot, and the wine is poured into small casks, wherein, after having fermented for two days, it is exposed to the air for a month. This is the wine that is generally exported. When of good quality it has a silvery, oily colour. The taste is sweet and mellow, with a peculiar earthy flavour, slightly astringent and aromatic, with garb body, but it is not drinkable until it is three years old. The Emperor of Russia has an agent who purchases 40 or 50 casks every year.

Colonies.

SOUTH AUSTRALIAN COPPER.—The rapid progress of the Wallaroo mineral district furnishes the strongest arguments that can be desired with regard to the expediency of extending all possible encouragement to mining enterprises. It seems but yesterday that the whole country (now dotted with flourishing townships and supporting a population of thousands) was a waste and tenantless scrub, and the question that generally forces itself upon the mind is why should there not be a score of Moontas and Wallaroos developed. It is notorious that indications of copper abound in every direction, nor is it reasonable to suppose that the indications are all delusive. Perhaps no form of colonial industry is so generally beneficial as copper mining. A vast amount of labour must necessarily be employed, and the market thus created for every description of colonial produce is of immense importance to the farmer, stock-owner, and to the commercial public generally. There should be no restrictions, no difficulties, no impediments whatever. Every man should be free to search for copper, and any rental or other charge the state may think fit to exact should follow and not precede that search. If the pros-

pector finds nothing the State should take nothing, and the most thoroughly liberal arrangements should be framed with a view to facilitate and encourage a description of enterprise of such unequalled benefit to the community. The total population of the Wallaroo district, so late an uninhabited desert, cannot be less than from 6,000 to 6,500 souls, as follows:—Kadina and Wallaroo miners, 2,200; Wallaroo, 2,000; Moonta and Moonta mines, 2,000; woodcutters, carters, and others living in the bush, 300; making a total of 6,500 souls.

PHORMIUM TENAX (SOUTH AUSTRALIA).—Large quantities of this plant have been found growing on the mallee scrub of the Lachlan Plains. The flax is from three to four feet high, and from one to two inches broad. It is stronger in its fibre than the New Zealand plant, and seems to be exempt from those oily properties that render the latter so difficult to convert into useful purposes. It is believed that by the aid of the small steamers running up the rivers the South Australian settlers will be enabled to collect vast quantities of the article and send it up to Melbourne. Some specimens have already been forwarded for the purpose of being tested.

SOUTH AUSTRALIA.—The great extent of the work yet to be accomplished in exploring the northern interior is shown by the frequency with which startling rumours relative to that part of the continent are received in Adelaide. Recently, much interest was excited by the report that a stockman in the employ of Messrs. Levi and Co. had discovered a large river flowing from a north-easterly district into Lake Eyre, a report which leads one to hope that the greatest problem of Australian geography has been solved, and that a question of the vast interior basin or inland sea in the north of Lake Torrens may at length be set at rest.

Obituary.

The Earl of CARLISLE died, at his ancestral seat, Castle Howard, Yorkshire, on the 5th instant, after a protracted illness. He was the eldest son of George, sixth earl, by the Lady Georgiana Dorothy Cavendish, eldest daughter of William, fifth Duke of Devonshire. He was born in April, 1802, and educated at Eton, and Christchurch, Oxford, where he obtained both the Chancellor's prize for Latin verse, and the Newdigate prize for English verse, taking his B.A. degree in the highest honours. At an early age he entered Parliament as member for the borough of Morpeth, which furnished his own courtesy title. From 1830 till 1841 he sat as one of the representatives of the important constituency of the West Riding of Yorkshire. In October, 1848, he was removed to the House of Peers by the death of his father. Whilst holding a seat in the House of Commons, his lordship filled the office of Chief Secretary for Ireland from 1835 to 1841, under the Lord-Lieutenancy of the Marquis of Normanby and his successor, during a period of great excitement and difficulty; and it was whilst holding this office that he acquired that experience and popularity which rendered him afterwards so well qualified for the discharge of the viceregal functions. From 1846 to 1850 he was Chief Commissioner of Woods and Forests, and from the latter date to 1852, Chancellor of the Duchy of Lancaster. With the exception of the period of Lord Derby's second brief administration in 1858-59, the Earl of Carlisle held the Lord-Lieutenancy of Ireland from the month of March 1855, down to his retirement in September, 1864; a term almost unexampled in its duration. In that capacity he devoted much labour and pains to the development of the agricultural resources of Ireland, and to the spread of a general system of liberal and enlightened education. The noble Earl was the author of several works, of some reputation, the best of which are his "Diary in Turkish and Greek Waters," "Lectures and Addresses in Aid of Popular Education," and "A Lecture on Travels in the United States of

North America." Only a few months ago he presided over the proceedings at Stratford-upon-Avon, in commemoration of the tercentenary celebration of William Shakespeare. His lordship was elected a member of the Society of Arts in 1851, and served the office of Vice-President.

Publications Issued.

PICTURE BUYERS AND AMATEURS' GUIDE, THEORETICAL AND PRACTICAL, by Théodore Lejeune. (Paris: Benouard, three vols. 8vo.)—This useful and important work is the result of the long labour of a gentleman whose position and reputation give it special claims to attention. M. Lejeune is a painter, entrusted with the delicate duty of restoring the pictures in the Imperial galleries, public and private; and he is also conservator of the collections, amongst others, Duclâtel, Benoit, Fould, and Morny-Soult. The object of the work, to quote M. Lejeune's own words, is to supply an exact classification of all true masters, in every style and of every school, together with an enumeration of their copyists and imitators, in order to assist amateurs in their researches. The first two volumes only have yet appeared; they contain an enormous amount of information, compiled by the hand of a master. The early chapters treat of general matters, such as the principles of the art, and its technology, the methods of recognizing copies, the fabrication of false pictures, the means employed for fixing the artistic and commercial value of pictures, and the various systems of restoration and cleaning in use; and, upon these points, the long experience of M. Lejeune, and the judicious and impartial tone of his remarks, render him an admirable teacher. In the body of the work the various schools are treated separately, and short, judicious appreciations given of each master, together with a list of his works, whether in public or private galleries, and the prices which they have fetched from the earliest known sales to the present time. The long lists of private collections in England evince the industry which M. Lejeune employed when visiting our country, the whole being furnished with an elaborate index of great importance. The third volume will include, amongst other matter, a Dictionary of Monograms, with fac-similes of a large number discovered or corrected by the author himself.

HISTORY OF INVENTORS AND INVENTIONS. By Emile With, C.E. (Paris.)—The object of this little work is to inform inventors of what has been done, and to help them, if possible, to avoid wasting their time, energies, and money, in going over ground that has been beaten before. M. With has also his peculiar theories about the methods of assisting inventive spirits and rendering their inventions fruitful.

OBSERVATIONS MADE AT THE OBSERVATORY OF PARIS DURING THE YEAR 1863.—Such is the title of a publication just issued by M. Le Verrier, the Imperial Astronomer; it contains only the results of observations, their discussion being reserved for the *Annales* of the Observatory. It appears that the number of fundamental stars now registered amounts only to about 600. Great improvements are being made, not only in the means of observation, but also in the relations between the observatories of various countries; an agreement, for instance, has been made between M. Le Verrier and Professor Airy that the results of the labours of each shall be recorded in the publications of the other. The French *Bulletin Météorologique* has in the same spirit been re-named the *Bulletin International*.

Forthcoming Publications.

LES BIJOUX ET LES GEMMES DE LA COLLECTION DU LOUVRE.—Etched by Jules Jacquemart, with explanatory letter-press, by Henri Barbet de Jouy, Conservator of the

Musée des Souverains, and of the middle age and renaissance collections in the Louvre. The first portion of this interesting and important work will appear in February or March next. Everyone acquainted with the Louvre during the last ten years, will remember the little dark room in which were kept the vases in agate, rock crystal, jasper, sardonyx, lapis lazuli, and other stones; the chased and jewelled vases, cups, swords, and other curiosities which had been the property of the kings or queens of France, from the time of Childeric to that of Marie de Medicis. Two years ago this splendid collection was disinterred from the vault-like chamber, and arranged with the contents of the two above-named departments, the cups, vases, enamels, and other objects being admirably arranged in the magnificent Galerie d'Apollon, which, for many years, had served no other purpose than that of a passage to the great picture-gallery. Here the beautiful works of the great artists of the Italian period, and the curious productions of their imitators, are seen to great advantage, and form one of the finest collections of the kind in Europe. Monsieur Barbet de Jouy, the keeper of this portion of the collections in the Louvre, is now engaged in the production of a catalogue of the contents of these galleries, which will shortly be ready. The forthcoming work, to which this notice alludes, will be no catalogue, but a collection of etchings, representing about one hundred of the rarest or most beautiful objects in the two collections—arms, vases, crystal cups, coffers, reliquaries and ornaments illustrative of industrial art from the earliest days of the French monarchy to the time of Louis the XIV. inclusive, each plate being accompanied by historical and technical notes. The latter will be from the pen of M. Barbet de Jouy, whose reputation and position give them special value; and the former are the work of M. Jules Jacquemart, one of the most able of the French *aquatortistes*. This young artist has already achieved a high reputation by his illustrations of his father's work, "The History of Porcelain;" of the elegant publication of the house of Techner and Co., of Paris, "The History of Bookbinding;" and by some charming fugitive productions of various kinds. We have been favoured with a sight of the plates already executed, and of the drawings for others, and we have certainly never seen more brilliant effects in black and white than those which M. Jacquemart has succeeded in producing in his reproduction of some of the crystal objects submitted to his pencil. Colour is not amongst the means employed, and therefore the etchings in question cannot supply the million with representations, *fac-similes* of the curious objects in question, but the artistic eye will revel in these etchings, which not only reflect the spirit of the great artist workmen of the middle ages, but fix on the plate the beautiful effects of light playing on surfaces of the most complicated outline in an extraordinary manner. The first part of this work, which will consist of three livraisons, will contain thirty-two plates, and as many sheets of descriptive history, and will include, amongst other subjects:—the sword of Childeric, with the crystal ball which accompanies it, and which is supposed to have been used by the Merovingian monarch, as eastern potentates still use similar balls, to produce a pleasant sensation of coolness to the hand; the vases of St. Louis; the sword of Charlemagne; the vase of Aliénor, queen of Louis VII.; the agrafe of the royal mantle of Saint Louis, an immense diamond-shaped clasp or brooch, weighing at least two pounds, and decorated with precious stones apparently of great value; and several other interesting objects. An attempt to delineate gold, silver, and gems by means of the etching point, seems, at first sight, as hopeless as painting the rainbow in Indian ink, but for all purposes of art, M. Jacquemart's etchings are true and admirably effective; as a French critic said of our Turner, "he has tried to paint *light* and has very nearly succeeded."

Notes.

KILLING ANIMALS WITHOUT PAIN.—Dr. Mac Cormac, of Belfast, writing to the *Northern Whig* on the painless extinction of life in animals designed for human food, proposes carbonic acid gas as a suitable agent for this purpose. His method would be extremely simple, and certainly would be an immense improvement on our present practices, which are still as barbarous as they were in the darkest ages. A carbonic acid gas generator of suitable dimensions, fed with a little chalk and sulphuric acid, must be had to hand. The sort of generator made use of by the soda water manufacturers would answer every purpose, even on the largest scale. The gas might be conducted by a pipe or duct into a wooden reservoir or chamber, for carbonic acid gas is so much heavier than air, where the animals should be led. Even gas mixed with air would suffice. No sooner should the line of the air rise above the level of the zone of respiration than as in the case of the *Grotto del Cane*, or the brewer's vat, the animal would at once fall prostrate and insensible, and without experiencing any appreciable pain or suffering, expire. A sort of India-rubber hood or bag could otherwise be adjusted to the creature's head, and, when so adjusted, the gas might be led on by a treddle pressed by the operator's foot. The instant the gas should surround the respiratory outlets, the animal's consciousness would cease. In order to prevent reanimation, the creature would have to be left a few minutes untouched, after which the butcher might resume his functions. Some persons may, perhaps, entertain an objection to the flesh of animals that have not been bled. But the abstraction of the blood, if desired, may as readily be effected after death by this process as when it is taken away in the usual manner. But the doctor strongly urges the discontinuance of the blood loss altogether. The butchers' prejudice about well-bled meat is one which they have inherited from their superiors, and has no colour of support. Dr. Mac Cormac maintains, whether in reason or fact.

PAROCHIAL INDUSTRIAL EXHIBITION.—The clergyman of Amberley, near Stroud, the Rev. R. Edward Blackwell, is actively engaged in getting up an industrial exhibition among his parishioners, and he explains his scheme in a letter addressed to them, from which the following extracts are made:—"You all know how many evils and how much unhappiness, idleness, during the hours of a winter evening, too frequently leads to. That person, then, is your friend who will suggest to you any occupation which may amuse you—which may put some money into your purse—which may keep you at home, and which, in many other ways, may indirectly be for your good. Many of you are clever in making certain things; one can do one thing, and one another. If you will only try, you will find that you can do many more things than you think you can. This trying will be very useful to yourself and others, for one person working will soon set another person a-going. My plan, then, is to try and set all of you, men and women, boys and girls, to work in a pleasant way in your own houses, at your odd moments, during this winter, and for you to gain something by it. At some suitable time in the spring I should like to have in our school-room what we may call an 'Industrial Exhibition.' During the winter months I would have you all work for this, according to your own different tastes and powers, one making one thing, and one another. Everything you make will be your own. At the time fixed for the exhibition, I will endeavour to gather together our friends throughout the neighbourhood, and sell for you the things you have made, if you wish them to be sold. I do not promise to sell them, but I will try to do so; if we cannot sell them they will be returned to you. Every article exhibited, I would suggest, should have the name of the maker written upon it, so that your friends will see by

whom every article is made. Let me mention certain things which one and another of you can do, or make, and which I have seen you at different times doing and making as I have called in at your houses:—Baskets—all sorts, all sizes, made of anything, for workmen to carry their meals or their tools in, or for anything else. Work in straw, or rush, or willow, or fern, or grass—mats, house-maids' kneelers, flower pots, bee-hives, cradles for babies or dolls, &c. Rustic seats, small and large—garden tables, stands for flowers, &c. Models—any kind, of any thing. Works in wood—picture frames, towel-horses, cap-stands, boxes, knife-trays, washing-stands, wheel-barrows, rough and smooth, large and small, &c. Works in stone, carved ornaments, vases, flower-pots, sun-dial stands, &c. Needlework—all kinds, patchwork quilt, bags, garden bonnets, knitting, netting, knotting, anything. Birds stuffed—collections of insects, &c. Turning—any thing useful, pegs for hats, for door handles, and for tobacco stoppers. Sticks for tying flowers to—bundles, in dozens, of hazel sticks, or neatly split wood, or turned wood. Labels for flowers in dozens; little boys might make these. Odds and ends—bits of cloth made useful, boys' caps, easy slippers, table covers, shoes made somehow and with anything, drawings, children's toys, dolls, small wheel-barrows, fossils collected from quarries and cleaned, glass covers for flowers, collections of different mosses, or winter flowers in pots or dried, &c., &c." He then suggests a committee of parishioners, and goes on to say—"If the committee see many working, and the thing likely to be a success, they would, previous to the exhibition, print a catalogue of the principal articles about to be exhibited, with the names of the makers. In certain cases the committee might lend a few shillings to buy wood, locks, or other things, as might be required, to be repaid when the articles were sold. The exhibition must be strictly confined to persons living in the parish of Amberley, or to those who belong to the Amberley church or schools. Every article exhibited must be made entirely by the person who sends it. Combined with the industrial exhibition, I would suggest that any friends who have objects of interest to exhibit should be requested to lend them for public exhibition on this occasion; the one exhibition would thus add interest and give power to the other. The exhibition to be open two or three mornings and evenings. The Amberley 'Industrial' band will attend, when able. None of the things sold to be removed till the exhibition is over. Such, dear friends, is a rough plan of my scheme. I am sure it would answer, and do good, if you would all, big and little, men and women, only try to do your best. Let everybody make a something, however small or simple. Do not be shy, or hesitate to join our band of workers. Let every person in the parish if possible be an exhibitor, and try and make something which will do him credit. Great moral benefits must result if we endeavour to spend our winter evenings in a profitable way. Let us look upon this effort in this light; let us all remember the end we have in view; let a family work together in common, and it must produce family love and union. The hearts of the fathers will be turned towards their children. If a small sum of money could be raised, we might bestow a few presents on those amongst our poorer friends, where industry and ingenuity had been manifested, and where there had been persevering effort, amidst poverty and difficulty."

Correspondence.

STATUES OF EMINENT MEN.—SIR,—What has the Council done with the Committee on this subject? I hope the Committee is to be re-appointed, and that the following extract from the *Times*, of November 20th, will be read by it. The Thames embankment will afford even a finer sight than a boulevard for an avenue of

statues, and I suggest that the council put themselves into communication with the Metropolitan Board of Works:—"It is true that no city in the world has undergone such transformations as Paris for the last ten or twelve years. Streets of portentous length have been cut through masses of masonry, old or new, as they happened to be in the way, laid bare recesses the very existence of which had been almost unknown to the ancients of the other quarters, and penetrated into alleys and winding lanes, the abode of pestilence and crime, and through which light and air had never filtered. Fountains, gardens, and squares stand where only a few years ago no human habitation was seen. This is not enough. What has hitherto been done is but the solid portion of the monument which is meant to perpetuate the memory of Napoleon III.—the mere masonry, the grosser part of the design. Stately mansions have arisen, as if by magic; there is a very wilderness of boulevards; sewers run in all directions underground; squares are planted with trees; and masons, blacksmiths, carpenters, &c., have done their best. The substantial and the useful being now so much advanced the moment is come for the ornamental, and when the mechanic must give way to the artist. People talk of a double road of statues starting from the Place du Trône, traversing the Boulevards and the Champs Elysées, and terminating at the triumphal arch of the Place de l'Etoile; that is, from one extremity of Paris to the other. Those statues, in marble or in bronze, are to reproduce all that was most celebrated in Monarchical, Republican, and Imperial France, so that in this open-air museum the French may see at a glance all that their country has produced of what was glorious in war, in letters, and in the arts; and that the very omnibus drivers and hackney coachmen may read as they run the lives of these worthies."—I am, &c., F. S.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

Dec. 21.—The Articles sent in Competition for the Art-Workmanship Prizes will be Exhibited; and a short Review of the Society's past and present action in the Promotion of Industrial Education, by S. T. DAVENPORT, Esq., will be read.

CANTOR LECTURES.

"ON THE REPRODUCTION OF NATURAL FORMS BY ART AND MANUFACTURE." By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

Dec. 19.—LECTURE II.—Demonstrations of the unity of plan in the external forms of animals, the just appreciation of which facilitates the work of the artistic producer, and adds to the enjoyment of the intelligent possessor of works of art.

JAN. 16TH, 1865.—LECTURE III.—On the varieties of artistic treatment of the forms of animal and vegetable life—pictorial representation; conventional ornamental, allegorical, and symbolic combinations of animal forms.

JAN. 23RD.—LECTURE IV.—On the fitness of designs, and their adaptation to the conditions of the materials in which they are to be produced. (Demonstrated by metal-work processes, sand-moulding, casting, and chasing).

JAN. 30TH.—LECTURE V.—On Ceramic Manufactures, with the Influence of the material on the design and its successful production—modern Terra-Cotta, Della Robbia ware, Majolica, and Parian.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture. A set of tickets for this purpose has been sent to every member.

Proceedings of the Society.

CANTOR LECTURES.

"ON THE PRODUCTION OF NATURAL FORMS BY ART AND MANUFACTURE." By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

FIRST LECTURE.—MONDAY, DEC. 12.—INTRODUCTORY.

MR. WATERHOUSE HAWKINS delivered the inaugural lecture of his course in connection with the Cantor Series of the present session. The subject to which he especially desired to direct attention was the application of natural forms to Art and Manufactures. In his introductory remarks he referred to the greatly advanced appreciation of Art by the English people since 1851, and pointed out the educational advantages which had resulted from the Great Exhibition, by the establishment of a National Museum of Art Industry at South Kensington, a collection in connection with which the Government Schools of Design were established, and which, in its intrinsic merit and arrangement, was unequalled by any other similar museum in Europe. Notwithstanding the improved appreciation of Art by the public, and the advantages which existing Art collections afforded to the student and workman, he nevertheless deplored the inability of the English artist to produce designs suited to the requirements of the British manufacturer, equal to those produced by the foreign designer and artist—this was particularly evidenced by the fact that in the Exhibition of 1862, nearly every important work exhibited by our great Art-Workmanship manufacturers had been produced from the design of some foreign artist. He then proceeded to discuss the reason of this deficiency of the English artist, and stated that he considered it resulted from the nature of the training to which Art-students were subjected in England, as compared with the system pursued in continental countries. In England the Art instruction tended to create skillful copyists, great precision, and steadiness of hand in the use of the pencil, but at the same time crippled the mind, whereas on the Continent the student was taught to take broad views of

Art by observing the structural forms of objects in nature, a system which left the mind and hand much more free. He believed that the Englishman's impediment was not a want of material in which to produce, nor yet examples to study, but resulted from a heavy drill, which created good imitators, but did not tend to create inventors. In order to invent or create successfully good designs for the Art manufacturer, it was necessary that the artist should possess a thorough knowledge and appreciation of the structure of natural objects, without which knowledge it was impossible for the draftsman to adapt the frames of men or animals to the requirements of the ornamentist and the processes of production, and ornament, if produced without a knowledge of structure, inevitably resulted in imperfect drawing or unnatural distortions. He then proceeded to point out that one universal law of structure pervaded the whole of the animal kingdom, a knowledge of which enabled the designer to correctly represent and apply the conception of his mind to the ornamentation of matter; and, by means of diagrams which he drew upon the black board, showed that man in an erect position could readily be made to represent a lion, as commonly drawn in Heraldry, stating at the same time that, structurally, the two were identical. He then referred to the importance of natural history museums in an Art point of view, and called attention to the method employed by Mr. Waterton of preserving skins of birds, animals, and reptiles, by the use of corrosive sublimate dissolved in spirits of wine, and urged the importance of natural forms being preserved truthfully in an artificial state, as otherwise the specimens tended to mislead the student rather than to instruct him in the flowing lines and graceful forms so commonly to be found in the animal kingdom.

FIFTH ORDINARY MEETING.

Wednesday, December 14th, 1864; Lord Dufferin, K.O.B., in the chair.

The following candidates were proposed for election as members of the Society:—

Bayley, John C., 1, Park-place-villas, Maida-hill, W.
Buxton, William, Lime-tree Lodge, Rotherhithe, S.E.
Hancock, Henry J. B., Duke's-hill, Bagshot.
Knight, John Peake, South Eastern Railway, London-bridge, S.E.
Lowe, John Stanley, 31, Cornmarket-street, Oxford.
Melliss, George Whalley, 17, Talbot-terrace, Westbourne-park, W.
Parnell, Hugh, M.A., 3, New-square, Lincoln's-inn, W.C.
Strachan, Charles Henry, 51, King's-road, Camden-town, N.W.
Vincent, Henry, 28, Mornington-crescent, N.W.

The following candidates were balloted for and duly elected members of the Society:—

Barnes, Joseph, 5, St. Thomas'-street, Borough, S.E.
Baton, John, 42, Brewer-street, Golden-square, W.
Dear, Alfred, Pavilion, Belgravia, S.W.
Dear, Arthur, Pavilion, Belgravia, S.W.
Forristall, Michael, The Hermitage, Forrest-hill, S.E.
Grundy, John, The Middle Temple, E.C.
Hall, J., 29, Warwick-square, S.W.
Huth, Edward, Oakfield Lodge, Huddersfield.
Lane, William James, 5, Studley-villas, Studley-road, Clapham, S.
Lord, James, St. John's Lodge, Wandsworth-common, S.W.
Monteith, James, 38, Duke street, St. James's, S.W.
Moss, William H., 19, Parliament-street, Hull.
Rohussen, Theodore Anthony, 9, Friday-street, E.C.
Saunders, Edwin, 13a, George-street, Hanover-square, W.
Schweizer, J. J., 28, Poole street, New North-road, N.
Scott, Rev. C. B., 19, Dean's-yard, Westminster, S.W.

Turner, Henry, St. Joseph's road, Higher Tramere, Birkenhead.

Twentyman, William Holme, Manor-hill, St. John's-wood, N.W.

Vaudrey, Henry, 10, Norland-square, Notting-hill, W.
Walkei, G. H., Rugby.

The following Institutions have been taken into Union since the last announcement:—

Knutsford, Penny Readings.

Preston, Institution for the Diffusion of Knowledge.

The Paper read was—

ON THE RECENT PROGRESS AND PRESENT STATE OF INDUSTRY IN IRELAND; AND THE DUBLIN INTERNATIONAL EXHIBITION OF 1865.

By SIR ROBERT KANE, F.R.S., PRESIDENT OF QUEEN'S COLLEGE, CORK, AND DIRECTOR OF THE MUSEUM OF IRISH INDUSTRY, DUBLIN.

At the request of the Executive Committee of the Industrial Exhibition, which is to be held in Dublin in the summer of next year, I have undertaken to bring under your notice this evening some explanation of the circumstances under which that Exhibition has been undertaken, and the arrangements which have been made to secure its success, together with such notice of the present position of Ireland, in an industrial point of view, as may enable the members and visitors of this Society, representing as they do so fully the industrial intelligence and commercial energy of this country, to judge whether the objects for which we in Ireland are now labouring are worthy of that sympathy and co-operation which I trust we shall be able to obtain. Almost simultaneously with the earliest efforts of this Society, to realise, by means of exhibitions, the actual position of British industry, similar exertions were made by those in Ireland, who were anxious to direct the energies of that country to the permanent and solid advantages of industrial pursuits; and amongst the means employed for that useful purpose, exhibitions of manufactures held a prominent place, these, although necessarily of a local and limited character, obtained a large amount of popularity and success. All such exhibitions, however, whether held here or in Dublin, could be considered but as the faint glimmerings of dawn heralding the full refulgence of the day when under the august Prince, whose loss the friends of intellectual and industrial progress will always deplore, the Exhibition of 1851 was inaugurated, and that unparalleled review of the aggregated productive forces of the world was opened to the assembled nations. The impetus thus given led to a greater development being allowed to the Exhibitions which took place in Ireland immediately after, as in Cork in 1852, and especially in Dublin in 1853. The objects were no longer limited to Irish manufactures, as they had previously been, but the British and foreign manufacturers were invited, to render the Exhibition in Dublin, as in London, really international. The Dublin Exhibition of 1853, for which a building admirable in its adaptation had been provided by the liberal enterprise of Mr. Dargan, was remarkable for the introduction of Fine Arts as a leading department, and was honoured by the presence and approval of Her Majesty the Queen and her illustrious Consort.

The great International Exhibition of 1862, which, after the interval of eleven years, had renewed with still greater richness and completeness of illustration the glories of 1851, had naturally suggested that after a similar interval an International Exhibition should be held in Dublin. It may be stated that an Exhibition has this year been held at Dublin and attained considerable popularity. Being limited, with the exception of machinery, to the display of objects of Irish manufacture, this Exhibition was on too small a scale to represent in any

degree the progress which foreign and domestic industry has made within the last ten years.

The opportunity of which it is now proposed to make use, in order to organize in Dublin an International Exhibition, which shall be the worthy successor of the great successes of 1851, of 1853, and of 1862, has arisen from the fact that a number of gentlemen, of whom it is only necessary to mention the names of the Duke of Leinster, of Mr. Guinness, and of Mr. Dargan, possessing at once the inclination and the power, have undertaken to provide for the citizens of Dublin a great winter garden and buildings containing concert and lecture rooms, supplying, but on a smaller scale, the resources and enjoyment of the Crystal Palace at Sydenham. An independent Executive Committee having been formed to organize and carry out an International Exhibition, the Directors of the Winter Garden have most liberally placed their fine buildings altogether at the disposal of the Committee for that purpose, and the Executive Committee have gladly availed themselves of this truly patriotic proposal. The Exhibition will, therefore, be organised under extremely favourable conditions, as all that in other previous occasions had entailed the greatest amount of expense, of responsibility, and of risk, will have been spontaneously and all but gratuitously provided, whilst the authority and direction is preserved entirely in the hands of the Executive Committee. The great advantage which will thus naturally result to exhibitors in the arrangement of their articles will be easily understood, and it has been arranged that all funds arising from the receipts above the payments of the expenses incidental to the Exhibition, shall be vested in a Committee of noblemen and gentlemen, under whose direction the excess shall be applied to public purposes for the advancement of Arts and Sciences in Ireland.

Such being the circumstances under which the proposed Exhibition is to take place, I shall very briefly notice the position which the building occupies. It is situated on the south side of Dublin, and in what may be considered the most fashionable quarter of the city; close to the terminus of the railway which leads to the beautiful mountain scenery of Wicklow. The extent of space accommodation available may be found in detail by reference to plans which are in the office of this Society, but I need only say that the accommodation already at their disposal is very large, and there are, as I believe, now present, gentlemen representing the Committee of Advice and the Executive Committee who will be able, and I am sure willing, to supply information as to the details of space, much more precisely than I could attempt to do. The principal portions of the Exhibition will be located in the Great Conservatories of the Winter Garden,—constructions in glass and iron, rivaling the Crystal Palace itself in elegance of design, although of course much inferior in extent, and affording advantages as to supply of light and means of display which could not be surpassed.

Under those favourable circumstances it may be hoped that, not merely on public grounds, but even on the lower but more directly practical basis of individual advantage, we may hope for the co-operation of the manufacturers of Great Britain, who cannot fail to derive material benefit from bringing the products of their factories and workshops under the immediate cognizance of the Irish people. The Executive Committee have good grounds for expectation that the industrial resources and products of our Colonies and of the European Continental States, with scarcely an exception, will be adequately represented on that occasion. Gentlemen of great activity and intelligence have visited, on the part of the Executive Committee, the governmental authorities and the industrial centres of the Continental States; they have been uniformly received in a most friendly spirit, and have received promises of active co-operation. We shall thus have brought before the inhabitants of Ireland the most beautiful and perfect productions of the in-

dustrial enterprise and artistic genius of Italy, of France, of Germany, and of Belgium. We shall have, as I expect, very efficient evidences of what Ireland itself can do in the way of manufactures; and it is to be hoped that the British manufacturers, even satiated as they may well be with triumphs already gained, and somewhat fatigued from the exertions by which that success was earned, will still not allow an International Industrial Exhibition to take place without Great Britain being properly represented, the more when that Exhibition will be held under the august sanction of Her Majesty the Queen, who has most graciously been pleased to become its patron, and when the Executive Committee have reason to expect that the Exhibition will be honoured by the presence of their Royal Highnesses the Prince and Princess of Wales.

Among the elements of success to which the Executive Committee attach the greatest value, must be considered the support and co-operation which has been received from the Council and officers of this Society. By their assistance a London Committee of Advice has been formed, which has contributed materially to our success. The all-pervading and well-earned influence of the Society of Arts throughout the manufacturing world secures to its recommendation, or as I may say, to its endorsement, an attention that no other body could command; whilst the accumulated experience of its officers in everything connected with the organisation and management of Industrial Exhibitions has even already proved of the utmost value. The Members of the Executive Committee are therefore anxious that I should express how deeply they feel the benefits of the advice and assistance they have received from this Society.

Whilst making the arrangements which I have endeavoured to describe for procuring a full and satisfactory representation of the natural resources and industrial progress of our colonies and of foreign states, the Executive Committee has had its attention naturally directed to the position which the productions of their own country should occupy in the Exhibition. Two courses were open to them—the one, of carrying out the principle of geographical classification, which will be adopted as regards the colonies and foreign countries, and thus to arrange the manufactures of Great Britain and of Ireland separately; or on the other hand, to merge all separate insular existence, and exhibit under one head the industrial productions of the United Kingdom. Although the former plan might have tended to conciliate to the undertaking a good deal of local feelings and honest prejudices, the Executive Committee have decided upon adopting the other course, and propose to arrange that all natural and manufactured products of Ireland shall fall into their respective positions as elements of the great total of British industry, extending to the results of industry—that fusion of interests and of objects which has already made so much progress in the political and social relations of those two countries.

In taking this course, however, the Committee are quite sensible of the risk that the industrial productions of Ireland—which are so limited in amount and in variety, as compared with those of Great Britain—might easily be lost sight of, and pass unnoticed in the immensity of the results displayed by her more fortunate Sister; and that, although acting upon the purest motives, and taking a course which I am sure will be found to be correct, they might be the innocent means of an injustice being done to the manufacturers of their native land. This it is desirable to prevent, and hence I feel it my duty in this paper, which may be considered as in some degree a foreshadowing of the Exhibition which is to come, to supply a notice of the present condition of manufacturing industry in Ireland, not attempting to go into details, or to mention every department, but only such as may furnish an idea of what is being done, and what we may hope to be able to do in the way of successful manufactures.

Every person is familiar with the fact that—whilst in this country the great development of manufactures forms the characteristic of its social organisation and the foundation of its political strength—in Ireland the manufacturing industry has not attained any similar extension, and that agriculture, generally speaking of an imperfect kind, forms the principal means of occupation and of existence to the people. Hence the terrible results which followed from the potato disease, and consequent famine in the years 1845–46, by which not less than a million and a half of population was destroyed, and which, followed by a continuous stream of emigration, numbering not less than 80,000 a year, reduced the population of Ireland from 8,175,124, in 1841, to 5,798,967, in 1861. I do not feel called upon, or indeed here even authorised, to express an opinion as to how far this great diminution of population is to be regarded as a national misfortune or the reverse; it is impossible, however, not to recognise that, under at least two points of view, society has benefited by the changes thereby introduced: Firstly, the establishment of the Inbourned Estates Court, by which the position of landed property has been simplified, and the introduction of an improved system of agriculture facilitated. Secondly, the rate of wages has been very materially increased, and payments in money generally substituted for a complex system of allowances, which practically left to the agricultural labourer little beyond the mere permission to live.

A population thus specially devoted to agriculture in its simplest form can turn only with difficulty, and under great stimulus, to manufacturing operations, so much more complex in their nature, and requiring so much more of intellectual exertion for their successful prosecution. In fact, even in England the first introduction of the staple manufactures had been mainly due to the successive waves of foreign population, Flemings, Germans, and French, who, retiring from the political and religious persecutions to which they were exposed in their respective countries, sought the safety and refuge which England alone, then even as now, presents to all that peaceably land upon her shores. To the philologist a curious study is afforded in the technical expressions still employed in the every-day language of the English workman in various manufactures, marking the foreign origin of those trades, and even the time and circumstance of their importation.

Similarly in Ireland we were indebted principally to strangers for the introduction of those branches of manufacture which were subsequently carried on with most success; and in many cases the names most eminent, even at the present day, among our mercantile community, mark unmistakably the historical events which had deprived their native countries of the ancestors of such worthy sons.

The absence from Ireland of any abundant deposits of bituminous coal, such as occur in this island, and on which gift of nature has been built up the colossal fabric of England's industrial power, necessarily prevents the establishment in that country of those branches of trade in which the cost of fuel forms any very large proportion of the total cost of production. Hence, although possessing in abundance deposits of the richest iron ores, we have not had any successful establishment of iron smelting in recent times. The iron ores, however, both as earthy carbonate and as hematite, are now largely exported from Ireland to this country to supply the enormously-increased demand. Similarly, although large quantities of copper ore are raised in Ireland, principally in the southern counties of Cork and Waterford, the ore is shipped to Swansea to be smelted, as the large proportion of fuel which is required in smelting copper would render the progress in Ireland too costly to be profitably carried on.

In the case of the ores of lead and silver, however, the proportion of fuel necessary is not so large, and not merely are all the lead and silver ores raised in Ireland smelted in the vicinity of Dublin, but a large quantity of foreign

ores of those metals are imported for Irish smelting works, the produce from which is highly esteemed, not merely in the local but in the British markets. I believe that this department of mineral industry will be found very efficiently represented by Irish smelters in the coming Exhibition.

Although the smelting of iron ores and the actual manufacture of iron is not now carried on in Ireland, yet there is a very large amount of trade in the making of machinery, especially for the linen manufacture, of steam engines and water-wheels, and of late years of iron ships. This latter business has already assumed large proportions. The Messrs. Harland and Wolff, of Belfast, have built in the last ten years twenty vessels, of an aggregate tonnage of 36,913 tons, giving employment to about 1,200 men. The establishment of Messrs. Malcolmson, at Waterford, is similarly active, and employs about 300 men, turning out annually, at least, one first-class steamer, mostly above 2,500 tons burden each, and engaged in transatlantic voyages. The establishment of Mr. Pike, in Cork, is equally successful; whilst that of Messrs. Walpole, Webb, and Bewley, of Dublin, although only two years in existence, already gives employment to about 600 hands, and has completed five vessels, of which one of 1,434 tons burden, the *Knight Commander*, was almost the only ship that rode out uninjured the terrific cyclone that recently caused such frightful calamity at Calcutta. I mention these particulars to illustrate how much of industrial activity there already exists in Ireland, and how marked the extension of that activity in certain departments has latterly become.

A very large branch of mining industry in Ireland, that of iron pyrites or sulphur ore, becomes the basis of an extensive series of chemical manufactures, which, however, are limited, just as in the case of iron smelting, to those branches in which the cost of fuel does not form a preponderant proportion of the total cost of manufacture. In Dublin, Cork, and Belfast, large quantities of sulphuric acid, of chloride of lime, sulphate of soda, magnesia, &c., are made; the important branch of alkali making, as caustic and carbonate of soda, however, is not, as I believe, carried in Ireland beyond the manufactures of sulphate of soda.

In mentioning the absence in Ireland of deposits of bituminous coal of industrial importance, it is, perhaps, proper to mention that several extensive coal fields, yielding, however, principally anthracite coal, exist in the interior of that country, and are worked with success and profit. Their produce is, however, not so well fitted for manufacturing purposes, and is all employed for domestic purposes in their localities.

I cannot pass from the subject of Irish fuel without reference to what constitutes so important a feature in the scenery and the agriculture of Ireland, the Irish peat-bogs. The reclamation of those great tracts of land to the uses of agriculture, and the employment of those stores of peat to the purposes of fuel, have occupied, and very properly, a very large amount of attention; but, whilst recognising fully the importance of the subject, it will be seen that the progress of society and of the industrial arts in later years has divested the question of much of the paramount importance that formerly belonged to it. In regard to the restoration of the peat-bogs to agricultural purposes, the first and necessary element must be a perfect drainage, a measure of truly national importance, indispensable for the proper cultivation of even the best land, and, in considering which, the improvement of mere peat mosses cannot be held the primary object. But now that by the researches of Liebig, of Lawes, and others, the true principles of the growth of agricultural crops are understood; it is well known that even thoroughly drained peat will not supply the materials required for the production of food, and that the cost of supplying those materials, in the form of manures, if applied to the same area of land of more suitable constitution, will yield greater and more profitable returns. Hence, where ordinary farm land can be obtained,

is improvement is preferable, as a field for the employment of labour and of capital, to the reclamation of peat bogs.

Similarly, the altered circumstances of the country have deprived the question regarding peat as a fuel of much of the importance that formerly was attached to it. The facilities for internal intercourse afforded by the railway system which Ireland already possesses, and which tends every year to expand, together with the low rates of freight, which allows the introduction of sea-borne coal at moderate prices, all tend to limit the area within which peat as a fuel can be advantageously employed, and to confine its use to the vicinity of the bogs and to the agricultural population. The heating power of peat being, even when best prepared and driest, not more than two-thirds of that of coal, together with the greater cost of transport of a bulkier and less valuable article, place a limit to its economy which will determine practically the area within which it can be employed. The various plans proposed from time to time for the preparation of compressed peat have, therefore, been found not to possess the primary advantages which had been at first expected from them, although eminently successful in so far as producing a compact, convenient, and agreeable fuel, which in some respects, may deserve a preference over coal, although it cannot do so for general manufacturing purposes.

The soil and climate of Ireland has always been favourable to the growth of wool, especially of the longer stapled kind, and at an early period the quantities of Irish wool exported to England were considered to interfere so much with the interest of English wool growers as to lead to some harsh fiscal regulations. Owing to various circumstances of the country and of the times, the woollen trade of Ireland had declined very much indeed, until within the last few years, when it began to revive, and it is now every year rapidly expanding in extent of business and in the variety of articles made. Thus in Dublin, in Cork, in Waterford, and in various inland towns, woollen and worsted mills that had been abandoned have resumed work, mills already in action have augmented their number of looms and spindles, and new mills are being erected. This great improvement is partly due to the fact that the diminished supply of cotton has produced a general increase of activity in the woollen trade, and also to the excellent character which Irish-made woollen goods have acquired in the English markets, being practically free from those sophistications that are but too commonly in use. The actual expansion of this branch of industry within ten years is shown by the fact that the number of woollen and worsted mills in Ireland had increased from nine in 1851 to forty-three in 1863; being nearly 463 per cent.

The cotton manufacture exists in Ireland, but to a limited extent, and latterly, since the diminution of the supply of cotton, many mills have been altered from cotton to flax spinning and weaving, in order to meet the increased demand for linen goods. This has been the case to a great extent with the factories of Messrs. Pim, at Dublin, and of Messrs. Malcolmson, near Waterford. The latter, belonging to the same enterprising family which I have mentioned already in reference to the building of iron ships, is one of the most completely organised manufacturing establishments with which I am acquainted. It contains 31,000 spindles and 950 power-looms, with all the necessary machinery required for the spinning and weaving department. Being to a great extent isolated from other works they are obliged to depend on themselves, in many cases, for the construction and repairs of machinery, and hence there is attached to the mill a foundry and mechanics' shop, where machinery equal to any made in the best English workshops is constructed. The total number of hands employed by the Messrs. Malcolmson, in their various works, may be taken as averaging about 3,000.

The mixed woollen and silken tissues, which are known as poplins, or tabinets, have been considered as peculiarly an Irish fabric, but the manufacture was first introduced into that country at the beginning of the eighteenth century, by some Huguenot refugees. This branch of trade had of late years considerably declined, until the recent commercial treaty with France, which opened up the markets of that great country, where the rich tissues of the Irish looms were extremely popular. Since that time the poplin trade has been very active, every competent hand being fully employed until within the last three months, when a reaction appears to have occurred, which has somewhat diminished the demand. This interesting branch of trade gives employment, principally in Dublin, to more than 1,200 persons, of whom about one-fourth are employed by the Messrs Pim, a firm active in all that tends to promote intellectual cultivation and industrial habits, giving, in their various departments of business, occupation to over 1,000 hands, and providing not merely for the material wants of those in their employment, but practically evincing most praiseworthy interest in their moral and social life. By the example of such employers, labour is truly dignified, and leaders of industry vindicate their right to the high position which, in this country, has been so justly conceded to them.

Of all branches of industry, however, that which is of most importance to Ireland, from the amount of capital it represents, and the number of persons to whom it gives occupation, is the linen trade. I am indebted to the kindness of Mr. M'Ilwrath, secretary to the linen trade of Belfast, for much valuable information on that subject, and also to Mr. M'Call, of Lisburn, for many interesting particulars, of which I shall endeavour to lay before the Society such general heads as our limited time may allow.

The linen trade of which Belfast has been long the established head-quarters in Ireland had been rather falling off in amount, until the interruption of the supply of cotton by the American War called it into immensely increased activity. The contrast in this regard is well shown by the following figures:—In 1859 there were in Ireland 82 flax-spinning mills, containing 651,872 spindles, of which 91,230 were unemployed; whilst in 1864 there were 74 spinning mills with 650,744 spindles, of which but 8,860 were unemployed, whilst 50,638 additional spindles were in May last about being set to work. Further, in addition to the above there were employed in 1864, 14,648 spindles occupied in making thread, and five mills were in course of erection to contain 45,000 spindles. In regard to power-loom factories for linen, a similar remarkable increase is shown for the same period. Thus, in 1859, there were 28 factories with 3,633 looms, of which 509 were unemployed, whilst in 1864 there are 42 factories with 8,187 looms, of which but 258 are unemployed; 1,685 additional looms were about being set to work at the date of the return in May last. The introduction of the factory system into the linen trade, and especially the power-loom, is comparatively modern, the first spinning mills for flax in Ireland having been established about 1828, previously to which time cotton spinning was much more extensively carried on in Belfast than it has since been.

The great extension of trade and the benefit to the operative classes which followed this change, may be illustrated by the following fact:—When spinning and weaving were done by hand, the firm of Richardsons, of Lisburn, turned out from 15,000 to 20,000 pieces of goods in twelve months; that firm can now deliver 250,000 pieces of bleached goods in the same time.

As to wages, in the old days of spinning on the domestic wheel, the earnings were from 2s. 6d. to 4s. weekly, whilst at present in spinning mills the ordinary work-women make from 3s. 6d. to 6s. per week, and superior hands from 6s. to 8s. The best hand loom weaver can only make 6s. per week, out of which he has to pay charges which leave him only 5s., whereas an ex-

pert girl, who can attend to two power looms, can make 10s. per week clear. Thus the earnings of individuals have been materially increased by the introduction of steam machinery in the linen trade; and in regard to the total amount of employment, there were ten years ago, 17,000 persons employed in this trade in and about Belfast, whereas in the present year the number employed in the mills is 25,000, exclusive of the vast number of outsiders who indirectly derive their subsistence from that branch of manufacture.

Coupled with this development of the linen trade there has taken place a great increase in the quantity of flax cultivation in Ireland. During the Crimean War, when the Baltic trade was subjected to certain impediments, the quantity of land under flax was increased and amounted in 1853 to 174,579 acres, but on the restoration of peace, the Baltic trade being resumed, the demand for home-grown flax diminished, and the cultivation fell off to 91,646 acres in 1858. Since that time it has again progressively increased, and has now assumed proportions entirely unprecedented, the quantity in 1863 having been 214,099 acres, and in the present year having increased to 301,942 acres, which at an average of 35 stones of clean scutched flax to the acre, gives the produce of fibre at 10,567,970 stones, or 66,050 tons: and at an average price of 7s. 6d. per stone, the total value of the crop of the present year, is £3,962,989. This great increase of production is accompanied of course with corresponding increase of the export trade. The total value of linens exported from the United Kingdom has nearly doubled within the last three years, having been in 1863 £8,469,036, against, £5,193,347 in 1861.

A corresponding increase has taken place in the branches of steam engine and machine making connected with the linen trade. The foundries and workshops occupied in that way have fairly doubled in extent of business and number of hands employed, while wages have increased within the last two years from 10 to 15 per cent. Simultaneously, the general trade of Belfast has increased to such a degree, that in the year 1863 the imports amounted to £3,505,991, and the exports to £10,472,598. The tonnage of the port in 1861 was 920,800 tons, and the revenue £40,600, whilst in 1860 the tonnage of Belfast had been but 54,200 tons, and the revenue collected but £2,740.

Closely connected with the linen and cotton manufactures are the important industries to which the refuse and worn-out remains of textile fabrics are devoted, the manufacture of paper and pasteboard. This branch of trade is extensively carried on in Ireland, especially in the neighbourhood of Dublin. The quantity of paper manufactured annually at the time the duty was repealed, was between 9 and 10 million pounds. The advantage afforded to the introduction of foreign-made paper by the late commercial tariff has depressed the condition of the paper trade in Ireland as it has done in this country, but it may be hoped that the relaxation of the export duty on rags, which has lately been made in the Treaty of Commerce between France and Switzerland, will mitigate, after some time, the disadvantage under which the British maker is now placed. In regard to specially Irish interests, I may mention that the lower price of straw in Ireland has led to a very extensive manufacture of the low-class paper containing that material, and that a large proportion of the cheap literature of London is printed on Irish manufactured paper.

A very large source of employment is afforded throughout Ireland, especially in the northern districts, in the sewed muslin trade, which occupies, it is estimated, over 800,000 females. The products of this industry are generally sent into commerce as Scotch, the greater number of the firms giving out the work being of that country. Indeed, this class of occupations are curiously cosmopolite, and illustrate the tendency of industry to overcome the distinctions of country and of race. Thus in the trade of shirt making, by which con-

siderable employment is given in Ireland, I have been informed that for some large houses the shirts are cut out and sewn in Ireland, are then sent to Scotland to be washed, thence they pass on to London to be made up and prepared for sale. Most of the shirts, however, manufactured in that way are intended for exportation.

Minor industries of that class are, I am happy to say, being introduced and extending themselves in Ireland. Thus the making of ladies' corsets and crinolines was commenced in Dublin by the enterprise of Mr. Crotty, some few years back, and his firm now employ 700 girls, who earn from 5s. 6d. to 10s. per week, producing at the rate of about £60,000 worth of corsets per year, all of which, as I believe, are exported to this country. For it is a remarkable, and I believe a healthy characteristic of Irish manufactures, as they are now carried on, that they do not depend for their success on any excitement of misdirected though honest patriotism or protection. In fact, the prejudice is entirely the other way, and the Irish manufacturer meets much more ready customers abroad than he can find at home. This, however, is not peculiar to Ireland. Similar feelings are met with in every country; and it is most creditable to the manufacturers in Ireland, that in every branch their products find a welcome reception both in Great Britain and in foreign countries, grounded on the confidence which has been established in the honesty of the materials, and the excellence of their make.

It would be unsuitable, if, in speaking of Irish manufactures, I omitted noticing what had been long considered the staple manufactures of that country—porter and whisky. Of the latter, the production and consumption has of late years very much declined, the quantity of Irish made spirits entered for consumption having fallen off from 8,136,862 gallons in 1853 to 3,898,268 gallons in 1863. This enormous decrease is due partly to the increase of duty, but I believe in a greater degree to the improved habits of the people. A large increase in the production of ale and porter is shown by the returns of malt on which duty was paid, which rose from 1,576,148 bushels in 1855 to 2,234,947 bushels in 1863. This increase, however, is in great part represented by the development which the export trade in porter has received.

Those remarks will serve to illustrate in some degree the position which the Irish manufactures may be expected to take in the approaching Exhibition, and although, with the exception of the linen trade, not comparable in extent with the same branches of industry as carried on here, yet it will, I believe, be found that what is done is done well, and will establish their right to an honourable companionship with their fellow-labourers in Great Britain.

I am indebted to my friend Mr. Barrington, who, I hope, will have the honour, as Lord Mayor of Dublin in the coming year, to receive in a manner worthy of the city and of the great manufacturing firm which he so efficiently represents, some details as to the position of the soap and candle trade which is carried on to a considerable extent in Ireland, especially in Dublin; about 230 tons of hard soap and about 40,000 dozen pounds of candles being made weekly. This manufacture, which has been said to constitute a test for the civilization of a country, is steadily progressing in Ireland.

Under these circumstances, I trust that the manufacturers of Great Britain will not hesitate to lend their assistance towards rendering the Exhibition a sufficient representation of the productive power of our common country. Now that the intervening channel has been practically bridged by the splendid steamers which give to the passage more than the security and almost the comfort of the railway train, the journey from London to Dublin occupies but a portion of a day, we may by our uniting on the common ground of industrial fellowship, contribute to cement that union by which the greatness and the tranquillity of the empire is secured. The position and the prospects of Ireland have been represented

is very desponding colours. Her woes and losses have been eloquently traced to commercial jealousy and political misgovernment, and there has been but too much foundation for that charge. We have, as I hope, however, passed from the crimes and errors of an ignorant and bigoted age into a time when the blessings of education have taught all classes the true road to national prosperity, and when a more enlightened and tolerant spirit governs the relations as well of nations as of individuals. Scarcely beginning to recover from the fearful visitation of the potato famine, Ireland has had to pass during the last five years through a succession of wet seasons and bad harvests, entailing an annual loss estimated by the highest authority, Judge Longfield, at five millions annually, or 25 millions in the 5 years. No wonder then that her agricultural capital has not augmented during that time; that the quantity of live stock has not been multiplied; that the area under cereal crops has not increased. But, with all this, even with the emigration of a class which it would be desirable if possible to keep at home, the amount of crime has been diminished by one half, and of pauperism to six-tenths within the last ten years, whilst wages have risen as well in agricultural as manufacturing districts to a point practically equal to the cost of labour in this country.

Our visitors next year need not imagine that in crossing a narrow channel of the sea they will pass into a wilderness, where agriculture is abandoned and trade extinct, among a population, lawless and pauperized, abject and ignorant, whose only signs of national activity are outbreaks of political and sectarian strife, miserably caricaturing that grand struggle which settled the constitution of this country a century and a half ago. Under a surface of passion and discontent, which represents the real Ireland, and is every day melting away, the humanising influences of education, and of equal laws, have called forth a new and a better Ireland, a nation intelligent and moral, peaceful and provident, and willing for any work that may be set before them, seeking such work even in the most distant portions of the globe. Such a people require only fair and considerate laws and example to constitute themselves admirable rivals for industrial enterprise, and prove themselves by to participate in the prosperity and power of this empire. I regard, as highly conducive to that great end, that our British neighbours, especially those who are themselves engaged in industrial pursuits, should know of Ireland and of its people; that they should learn of the people and of the country as they now are, not by the newspaper exaggerations, or stories of a bygone time. Such means of calm and dispassionate view will be afforded by the opportunity of the exhibition next year; and—as I believe the result will be to state the position of Ireland and of its people in the eyes of those who are most competent to decide, as the most interested in the result—I do trust and expect that England and Scotland, as well as more distant foreign countries, will be well represented as visitors and co-operators in the approaching Exhibition.

DISCUSSION.

MR. POWERSCOURT, in responding to the call of the Chairman, would as Chairman of the Fine Art Department of the Exhibition, offer a few remarks. There can be no doubt that the Fine Arts could not flourish in a country which was not materially prosperous. Refinement and art were the children of education, and education in any country was not obtained without a certain degree of affluence. The history of the world showed that the wealthiest and most powerful nations had been the foremost in the fine arts. The emporiums of riches and commerce, such as Manchester, Liverpool, and other manufacturing cities, were places where at the present time the greatest encouragement was shown to painters and sculptors. Ire-

land, unfortunately, was not in the position of affluence and superfluity which England enjoyed. The causes of this state of things he need not enter into, but in a backward country like Ireland the difficulties were great, on account of many conflicting and antagonistic interests. It was, however, more than ever the object of any lover of his country to do what he could to promote the civilisation and refinement of his countrymen; and in cultivating a taste for the fine arts, he believed we should aid materially in this direction. Unfortunately his countrymen had not yet sufficient confidence in a rule which sought to place them as free citizens on a noble equality with the rest of civilization by means of education and refinement. He thought if all classes in Ireland gave more encouragement to the arts and sciences, it would tend to raise Ireland to the level of other countries. International Exhibitions were great promoters of intercourse, and friendly intercourse promoted mutual improvement. He was happy to add that the prospects of the Exhibition in that department over which he presided were most encouraging, and he had no doubt that the artistic display in Dublin, in 1865, would be of a very attractive character.

MR. VESY FITZGERALD said, more than anything else with which he was acquainted, these Industrial Exhibitions demonstrated the fact that individual effort, in the present age, attained the largest results when it availed itself of the power inherent in the principle of co-operation; for these exhibitions depended on the co-operation of class with class, of country with country, and of man with man. They produced fruit, and the production of fruit was what Lord Bacon held forth as the great recommendation of his system of Inductive Philosophy, which had formed the basis of the development of science and of material progress that had been witnessed by the last two centuries. All the education of the popular taste and faculties which was imparted by the study of the Fine Arts, was afforded in the most effective manner by these exhibitions. But they led also to an advance in artistic skill, and to the general improvement of manufacturing processes. The Committees appointed by this Society, in consequence of the last Great Exhibition in London, were calculated to be of great use in this way, and, without doubt, would prove to have been most useful, but it was, of course, difficult to know the exact nature of improved processes adopted by individual producers, until all idea of secrecy connected with them had passed away; so that it could not be immediately ascertained. New articles, and patterns of various goods, however, met one's eyes every day, the idea of which was taken from things seen in those Exhibitions. He would conclude by expressing his conviction that the principle of improvement inherent in these exhibitions was most powerful in its operation, and that the extent to which it might probably be felt was obviously impossible to estimate.

MR. HERCULES MACDONNELL, in responding to the call of the Chairman said, it was not his intention to enter into any of the many general topics which had been so well discussed in the interesting paper they had heard. He merely wished to add, as supplementary to what they had heard from Sir Robert Kane, a few facts which had come within his own personal knowledge, and tending to show that the exhibition was likely to be eminently an international one. As one of the Executive Committee, it fell to his lot to put himself in communication with foreign governments, and more particularly those of Southern Europe. He begged, in the first instance, to return his thanks to the members of this Society and to the officers of the South Kensington Museum, who had furnished him with information as to the best means of proceeding, and with introductions to those most likely to aid him in his object. They had supplied the much-needed compass without which he would have been unable to steer his course in this, to him, novel undertaking. He in the first instance went to France, and he was happy to say his application was not at once acceded to. The French

Minister showed great willingness to listen to all he had to say, but he required to be satisfied as to the soundness of the undertaking. The result was, that the Government was satisfied on that head, and decided that the enterprise was deserving of their support and co-operation. And here he might say the promoters of this exhibition did not feel themselves in the position of those who undertook a similar duty in 1862—viz., to solicit foreign governments to give pecuniary aid to the undertaking. It was felt by the promoters of the undertaking that all they could ask foreign governments to do was to forward the goods of their exhibitors to the nearest seaports, from whence the managers of the Exhibition would provide for their transport to Ireland, undertaking to send back the objects unsold to those ports, and to pay the insurance. In France he was happy to find that so able and enlightened a government gave its assistance and co-operation to the enterprise, Prince Napoleon, who was not only a prince, but a man of great talent and large experience in exhibitions, took up the matter warmly, and he (Mr. Macdonnell) had reason to think the opening of the exhibition would be honoured by his presence. Backed by the example of so great a nation, he next proceeded to Belgium, where, he was happy to say, he met with ready and almost enthusiastic co-operation, and many of those who acted as commissioners for the Exhibition of 1862 had undertaken the same duty in regard to the forthcoming Exhibition in Dublin. From thence he proceeded to Holland, where he met a very warm response, and that country would be well represented, and no doubt would acquit himself well in this contest of nations. After that he went to Frankfort, which, though not great in itself, was a most important commercial centre, and there a commission of men of the highest standing was formed, by whom would be brought together the varied products of the various States of Germany. He afterwards proceeded to Switzerland, and he had reason to believe that there would be a good representation of the special products of that country, and they were not few. Thence he went on to the Kingdom of Italy—now more important than ever—and there he found the government most willing and anxious to do what they could towards this enterprise, though they could not undertake a money expenditure for the purpose. He (Mr. Macdonnell) stated that pecuniary assistance was not asked for; all they wanted was the official patronage and encouragement announcing to their subjects that the enterprise was deserving of support and co-operation. He was happy to state a large committee had been formed in Turin, comprising the first men in Italy; and the question now was, not whether they should get objects from Italy, but where they should put them. Milan would send some of her best sculpture, and Florence would not be behind in artistic productions. In Rome, too, after some preliminary difficulties, he received the assurance of Cardinal Antonelli, and from the Pontiff himself, that it should not be their fault if Rome was not as well represented in Dublin in 1865 as she was in London in 1862; and he had since his return received a despatch, stating that a commission of the leading men of the country had been appointed to take charge of this matter. Austria was the next country he visited, and there the difficulties on financial grounds were as great as in any other quarter, which, however, he could not quite so readily meet, because he could not undertake to send a steamer to Vienna; but in this respect the ready assistance of the Rothschilds was accorded in getting a reduced tariff on the railways for conveying articles to the seaboard, and he had every reason to expect an excellent collection from Austria. From Bavaria and Munich, the great centre of mural decorations, there was a probability of some of those cartoons being sent which had not appeared in any previous exhibition. He believed every country in Southern Europe would be represented in its art and manufacturing productions. With regard to the usefulness and importance of such a display there could be no doubt. Sir Robert

Kane was quite right in saying there was no antagonistic rivalry between the progress or the genius of England and Ireland. On the contrary, he thought the one supplemented the other. The paper of this evening, as well as the discussion on it, would, he trusted, assist an enterprise whose only object was the advancement of their common country.

Mr. ANTONIO BRADY said he had been deputed to visit the north of Europe. He had taken the Scandinavian nations, and he had also good results to report. He had, however, met with the same objections on financial considerations as had already been referred to. The Swedish Minister had especially referred to the excessive expenditure incurred in the last Paris and London Exhibitions, which he was not prepared to recommend again. He was also met in many places with the idea that Ireland was a sort of Poland, in a state of anarchy and revolution, and there was no security for articles exhibited; and he was glad to find that Sir Robert Kane had given a very different and more truthful view of the general condition of the country. He desired to express his deep obligations to the officers of the South Kensington Museum, and especially to Mr. Owen, who had rendered the greatest service, not only by his advice, but by his letters of introduction to the leading foreigners who had been connected with the Exhibition of 1862. Having duly acknowledged the ready co-operation and courteous attention afforded by our ambassadors and consuls, Mr. Brady stated, that the encouragement he met with throughout the Scandinavian provinces was such as to enable him to assure those interested that most valuable contributions of artistic and manufacturing productions would be forthcoming from those northern nations. As regarded Denmark, unhappily he arrived just as that unhappy war, which had crippled the resources of that country, had closed. The enlightened government of that country, from the king downwards, had, after due consideration, promised hearty co-operation. The king, himself no mean artist, had promised to contribute to the Exhibition, and he (Mr. Brady) was confident in the belief that Denmark would be as well represented as any other country in Europe.

Mr. CHICHESTER FORTESCUE, M.P., having been called upon by the Chairman, said, as a member of the Colonial Department of the Government, he was glad to have the opportunity of saying, not only on his own but on the part of his right hon. friend at the head of that Department, it had given them great pleasure to have been the means of bringing this laudable enterprise before the notice of the colonies of Great Britain. He was not prepared to state in detail what the colonies respectively were prepared to do, but in general terms he might safely state that they were ready to respond to this invitation, and that the colonies of Great Britain would be properly represented in the capital of Ireland, as they had been in the capital of England. But, as an Irish member, he could not refrain from expressing his thanks to Sir Robert Kane for the extremely valuable and interesting address he had that evening delivered; and, more than that, he would express his thanks in the same capacity, if they would allow him to do so, to this assembly for having met here for the purpose of listening to and discussing such a subject as this. He thought it must strike many of them, as it struck him, while listening to Sir Robert Kane, how very great the contrast was between the former days to which he alluded and the present. He talked of days when Irish wool imported into England was considered a nuisance, but, among all the statements and evidence put before them by Sir Robert Kane, there was none to which he attached more value, or for which he was more grateful as an Irishman, than the hopeful spirit he had expressed in his address. He felt inclined to thank every Irishman—above all every distinguished Irishman—who, like the ancient Roman, did not despair of his country. He confessed they heard too much, both from the press of Ireland

and from public men, of that kind of despair which was apt to fulfil its own predictions. He confessed a good deal of blame on that score attached to the class of men to which his noble friend and himself might be said to belong—viz., to politicians. He did not use it as a term of reproach, though across the Atlantic "politician" was about the worst name one could call a man; but, happily, that was not yet the case on this side of the water. No doubt the last three or four years had been years of great trial to Ireland; but it was consoling, when unhappy, to know the cause of the unhappiness, and if they were suffering from misfortune to know its source, and look forward to its termination. He believed there would not be a doubt that Sir Robert Kane had told the simple truth. He had heard from Irish farmers and men of business that the temporary check which had been experienced—for it was nothing more than that—had only been caused by the exceptional disadvantages of the three last summers. It was a misfortune to a country to have but one string to its bow; and one of the great objects of this Exhibition was to endeavour to provide Ireland with other strings to her bow. He trusted what they had heard to-night would induce many in this room and out of it, and those of other countries, to visit Ireland for themselves, to see what she had done, and what she could do; and he hoped foreigners would see that the miserable and contemptible libels poured on Ireland from some quarters were odious falsehoods. They would find that Ireland was not another Poland, but, on the contrary, a country—no doubt with many things, like other countries, requiring correction—but a country well governed, and capable, by exerting self-reliance, of taking a creditable position by the side of this country as an integral part of it. He trusted that would be the effect of this great enterprise. He trusted large numbers would visit the Exhibition and would make that passage between England and Ireland which Sir Robert Kane had described in such glowing terms.

Mr. HENRY COLE, C.B., would merely call attention to one point which had not been touched on, either in the paper or in the remarks that had followed it. He hoped the Managing Committee of the Exhibition would provide for that which was now attracting great attention in London, and which might be made an interesting feature of the Exhibition in Dublin, viz., an exhibition of the industry of the workmen of Ireland, as a separate section. Of course the works of artisans and others would be exhibited among the manufactures, but he thought an attractive section might be made if the workmen of Ireland were inclined to show the fruits of their ingenuity.

Dr. BACHHOFFNER was anxious to know whether it was the intention of the Commissioners of the Dublin Exhibition to apply to the Government to pass a short Act of Parliament, as was done in the case of the Exhibition of 1862, for the protection of unpatented inventions.

Mr. MACDONNELL stated that the Attorney-General for Ireland would prepare such a Bill to be introduced on the assembly of Parliament.

Mr. W. HAWES remarked that hitherto the discussion of this able paper had assumed almost entirely an Irish character. As he thought the facts stated and the views taken by Sir R. Kane were equally important to them as Englishmen—equally important to the whole country as to Ireland alone—he hoped he might for a few moments call attention to the facts, to show how they as Englishmen were interested in the success of this exhibition. They could not see the progress of manufactures, of industry, and education; they could not hear that wages had been increased, that vice had diminished, and that the consumption of spirits had enormously decreased, without feeling that a country which perhaps had not hitherto raised the national character of the empire, was now progressing in a way which was calculated to make Ireland a source of great power and strength, and a country of

which England had reason to be proud. As Englishmen we could contribute to the success of this enterprise, which had been so energetically taken up by the Irish people themselves. That Exhibition must not be received as a mere temporary display. It would have a permanent and beneficial influence on the industry and commerce of Ireland. It would stimulate her to rely more on herself, to establish new manufactures, and make herself more independent; and force into activity and life those seeds of prosperity which had long been lying dormant. A competition would be produced which would urge on both countries to produce better articles than they had hitherto done, and thus would the closer connection with Ireland and her manufactures result in benefits to both countries.

Mr. HARTLEY expressed his opinion that much of the evil of the industrial system in Ireland would be remedied by a proper system of apprentice laws, by which the extension of skilled labour would be promoted, and a great want of the country supplied.

The CHAIRMAN said it was his pleasing duty to move that the thanks of this meeting be tendered to Sir Robert Kane for the admirable paper which he had been kind enough to read to them; and he only wished, that in doing so, he could adequately express what he was sure was the feeling of every one who had heard him. At all events, if he was not able to find words which would satisfy those whom he had the honour of representing, he could assure Sir Robert Kane there was not one in the room who more thoroughly appreciated the perspicuity, the moderation, and the truth of every single opinion and every single fact to which he had given utterance. He might be permitted to refer to one or two points in which he could especially confirm, from his own personal experience, the observations made by Sir Robert Kane. Sir R. Kane had stated it was to the development of Irish manufactures that they must principally look for the prosperity of that country. In that opinion he cordially coincided. As an Irish landowner, he had been painfully aware of the innumerable ills which had arisen as a consequence of the undue pressure upon the land of Ireland. In consequence of so very few openings, indeed, he might almost say, no other opening being afforded to the industry of the country, except that which was connected with the cultivation of the soil, the peasantry of the country had been reduced to a condition which was incompatible with their prosperity or their comfort. There was no Irish landowner who, if he was a conscientious man, could dare to accept for his land the competition prices which would be offered for it. Land was, in fact, almost a monopoly, and the consequence was, the margin of profit to the cultivator, which in other countries was amply sufficient for education, decent clothing, and comfortable housing, was in Ireland reduced to the smallest possible extent. He was happy to be able to confirm, from his own experience, what Sir Robert Kane had stated with regard to the enormous stimulus which had been of late given to the linen manufacture. He happened to live in the neighbourhood of Belfast, and he believed nearly every manufacturer in that town was making something like £1,000 per week at this moment. A personal friend of his own, who, having acquired an ample fortune, was about to retire from business, offered his mill for sale two years ago, at the price of £80,000, and was bid only £70,000 for it, consequently he retained it in his possession, and a few months ago he had the satisfaction of disposing of it for £180,000. Before he concluded, he thought he should be fulfilling the wishes of those present if he expressed their thanks to those two gentlemen who had acted as ambassadors to other countries on behalf of this Exhibition. He would now, on the part of the Society, return to Sir Robert Kane their most hearty and cordial thanks for the services he had rendered to them and to the cause of the proposed Exhibition, and of Irish manufactures. When, hereafter,

Ireland should have attained that position of eminence in that career of progress which he trusted was now opening before her, the name of Sir Robert Kane would be remembered in the catalogue of those men whose patriotism and devotion to their country had laid the foundations of her prosperity.

SIR ROBERT KANE expressed himself as much gratified by the kind manner in which his paper had been received, and also by the way in which the Chairman had been pleased to express the thanks of the Society on this occasion. He assured the noble lord and the Society there was nothing from which he expected more practical advantage to the cause of the prosperity of Ireland than the increase of mutual good feeling and co-operation between this country and his own.

BRITISH ASSOCIATION, BATH, 1864.

ON THE PRACTICAL PROGRESS OF NAVAL ARCHITECTURE IN OCEAN AND RIVER STEAMERS, TUGS, AND TOW VESSELS.

In the Mechanical Section, Capt. Andrew Henderson, C.N.E., A.I.C.E., read a paper on this subject, in which he entered upon the various types, from the *Leviathan* to the *Nautilus*, and systems of steering and towing, as shown in the summary of results of trials and performances in England and India, and illustrated the subject by diagrams, plans, and models, with tabular record of their relative dimensions, cargo, draft, displacement, and other elements of resistance, engine-power, and speed realised, and measured by dynamometer, the *plus*, *minus*, and *frictional* resistances of three types of vessels at three different speeds, giving their relative drafts and capability for cargo: with suggestions for improvements in the steering of the *Great Eastern*, and large iron-clads of the *Leviathan* type, and small iron-clads, rams, and gun-boats, similar to the *Assam Nautilus*, by the use of balanced rudders in bow and stern. The reading of the paper was prefaced by a reference to the models of the four types of river steamers and barges, the resistance of which had been ascertained by dynamometer at trials in this country in the *Nautilus*, or native type, the *Assam* type, as established on the *Burhampooter*, and the *Punt* type, or *Bourne's Patent Train of Articulated Barges*, tried on the *Thames*, *Tyne*, and *Clyde*, in 1859-60. The model of the dynamometer showed the mode of application to the tow rope, and a printed return of test trials was furnished of those as well as of the large *Indus* troop steamer, tried on the *Thames* in 1861, representing the European type of river steamers on the plans of a Government commission.

The sheer and deck plans of the European type, the *Punt* type, tried on the *Indus*, and of the *Assam* type and *Nautilus*, or native type, were shown in a comparative plan of midsections of ocean steamers and clipper ships, published with the paper read before the British Association, at Liverpool, in 1854, with suggestions for the improvement in the steering of the *Great Eastern*, *Warrior*, and other iron-clads. The author said, in explaining a subject so complicated, it was difficult to give in a small compass the results of experience of many years. In the early establishment of steam communication in India he took a leading part, and subsequently devoted his time and attention to improvement in the form and construction of river steamers, and making experiments in steering and towing with a view to economic transit. His nautical experience originated in service in her Majesty's ship *Bellerophon*, and her boats, and in merchant shipping in voyages to India and the Pacific, the coasts, ports, and rivers in India, China, and the Eastern Archipelago, the latter in a very fast-sailing old American privateer, and subsequently superintending the building and fitting up of the *Forbes* steamer, of 300 tons, and 120 H. P., as a tug on the *Hooghley*, and opening steam communication between India and China by towing the *Jemessina*, of 380 tons, from Bengal to China against the

Monsoon, in 1830. In 1831 he built the clipper *Water Witch*, 380 tons, in Calcutta (a model of which was shown) partly on a French model, designing himself the masts, sculls, rig, and fittings. After twelve successful voyages to China, she was dismantled, on the last, owing to the strain on the wing transom jamming the rudder. Based on this experience he designed the *Ariel*, with fuller after lines and round stern.

On his return to England in 1837, at the request of the late Lord William Bentinck, he gave evidence before Parliament as to steam communication in India, and after obtaining information from that eminent draughtsman, the late Mr. Waterman, he participated in the formation, in London, of the East Indian Steam Navigation Company and Assam Company, in 1839, the former proposing to the Indian Government to carry a monthly mail to the three presidencies of India in vessels of 2,000 tons, for a guarantee of £100,000 a year. The Assam Company was formed in 1839, by the union of Local and London Company to take over the Government tea gardens in Assam; and as a director of the Local Board, he designed and contracted for a steamer, barge, and portable saw mill, specially adapted for the service of the company, and as a Calcutta director, in 1841, tried and established the steamers on the Bengal river.

A model of the steamer, with bow and stern rudders, was shown on the table, the origin of the *Assam* type and balanced rudder system of steering. Between the *Water Witch* and *Assam* models are those of a first-class flotilla of the *Assam* type, tug and two auxiliary tow vessels, 35, 33, and 30 ft. broad, and 200 feet long, to carry 1,200 tons, 10 miles an hour, with 250 horse power. The *Sir James Melville*, 33 feet broad, 130 horse power, was sailed out with false bottom, as shown by the model and plan, and is now towing two barges similar to the trial barge, 30 feet broad, and has been profitably employed on the *Ganges* and *Burhampooter* since 1863, by the River Steam Company of Calcutta.

Three steamers, 35 feet broad and 170 horse power, similar to the trial barge of the *Assam* type, and his models, are now on the Bengal rivers, which he considered as the practical progress towards improvement in his large class flotillas, as exemplified by the drawing appended, shown on one-sixteenth inch scale, sheer and deck plan of tug and two tow barges, of the above breadth, illustrating the system of steering and towing with balanced bow and stern rudders and radial tow spar; and on $\frac{1}{2}$ inch scale the details and improvements in fitting balanced bow and stern rudders, resulting from the numerous trials in the experimental *Assam Nautilus*.

Proceedings of Institutions.

MANCHESTER MECHANICS' INSTITUTION.—On Friday evening, Dec. 2, a meeting was held in the Mechanics' Institution, Mr. O. Heywood in the chair, for the distribution to the pupils in the Institution school and classes of the prizes and certificates won by them in the last examinations. The Chairman said the Institution had about 1,300 members, of whom about 800 were life and honorary members. The classes of the Institution were better and more regularly attended, and more real industrious work done and more steadily done now than for a long period. The number of teachers in the day and evening classes was twenty-five, and to them the Institution was largely indebted for its present distinguished position. The number of general members of the Institution was, however, less than it was five or six years ago. Notwithstanding that the classes were better filled, and that more honours were obtained, the Institution did not retain its old members. The Directors had made efforts to overcome that disadvantage by establishing a billiard-room and a gymnastic class; but the fact remained the same,—they kept no hold on those who had got beyond the practical teaching

of the classes. That should not be. He hoped that, as they had done before, so again the Directors would succeed in striking out new lines and courses, so as to make the Institution as attractive and amusing as in other respects it was instructive. In 1858, the first year that the certificates of the Society of Arts were awarded, 19 certificates, in all, were taken by the students of the Mechanics' Institution. In 1859, the Institution took three first-class certificates; in 1860, two; in 1861, five; in 1864, 19 first-class; while 64 certificates in all were taken, and £8 in prizes. In 1863, the number of first-class certificates was seven; and of second class, fifteen. This year the first-class, as already stated, numbered 19; and second-class, 23. The number of third-class certificates was the same in each year, namely, 22. The increase this year was, therefore, mainly in the first-class. With regard to the Government Science Examinations, the Institution had in three years increased its first-class honours 2½-fold; in second-class honours fourfold, and in third-class honours twofold. Since last year the increase had been wholly in the first and second classes. The Institution this year took three silver medals and four bronze medals.—Lord Stanley, M.P., congratulated the members upon the flourishing condition of the Institution, which had preserved itself and its character through the vicissitudes of forty years, while many kindred institutions had either perished or been converted into club-rooms for the middle classes, or centres for party organization. The work of a Mechanics' Institution is to continue for such persons as desire it, and to extend the very limited and imperfect teaching which alone a school for the industrial class, or indeed for any class, can pretend to give. His Lordship continued:—A boy is taught in his school, well or badly, as the case may be, till he is twelve years old. If his parents are poor, he does not stop much longer; and for myself I value so highly the advantages for an early introduction to the practical duties of life, that I don't grudge that early departure. But if he leaves at that age, he can have got very little beyond the mere ground-work of knowledge, the power of reading, writing, and cyphering; and, for my part, I wish schoolmasters would recognise that fact more clearly than they do. I don't think they quite understand of how very little use it is stuffing children's memories with facts, or with what are supposed to be facts, to which no definite idea is attached. I have heard boys rattle over names of kings and countries when I was quite sure not one in fifty of them had any definite notion of what was meant by a king, or what the capital of a country was. I have always said, and always shall say, that if a child learns at school to read easily, and with pleasure to itself, to write well, and by that I mean distinctly, and to do common sums, the schoolmaster has done his share, and other agencies will complete what he has begun. People are beginning to find out what, if they would use their own observation more, and not follow one another like sheep, they would have found out long ago, that it is doing positive harm to a young child, mental and bodily harm, to keep it learning, or pretending to learn, the greater part of the day. Nature says to a child, "Run about;" the schoolmaster says, "Sit still;" and as the schoolmaster can punish on the spot, and nature can only punish long afterwards, he is obeyed, and health and brain suffer. I have nothing to say against hard work—brain work or hand work; I believe it to be healthy, and that at a ripper age those whom it injures are infinitely few compared with those whom it benefits. But you must let nature have her way. Three or four hours of attention are quite enough in a day for any child, and if you accept that principle it follows necessarily that the school must leave much undone, and that some other machinery of teaching is required, such as that provided here. It is the idlest folly to try to turn out men and women as you turn out manufactured articles, all done by one pattern. It takes some of all sorts to make up society. How often, in the upper ranks of life, one hears it said,

"So-and-so is a fine lad; he'll make a capital soldier, a sailor, or a colonist, but he has no turn for books." Do not mistake me. I think that the studious type of character is, on the whole, both the happiest and the highest. Men of that turn have pleasures and resources which others have not, and which never wholly fail. That is no small matter, because sheer weariness, dullness, the monotony of a life which is safe but not eventful, lead to half the mischief which men do to themselves and their families by falling into bad ways. All I say is (because we gain nothing by exaggeration), that those who take that line, those who care really for reading, and for self-improvement, will never, in any class, be more than a fraction of the whole. But then they are a very important fraction, important in the influence which they exercise, if not in their numbers. What we have to do, is to see that men of that type, in the less wealthy class, have a fair chance of developing such faculties as they may possess. Our business is to find the tools; let those who can and will use them; and that there will be, that there are many such, I do not doubt. The people of Manchester know what they are about too well to go on year after year spending money on a thing which gives them no practical return. It is often said, "Look at the very ablest and cleverest of your self-raised men, men that have had little or no instruction; very often they know next to nothing outside their own particular business." That may be true enough. Mechanical genius, or a turn for commercial enterprise, like any other gift, is born in a man. That is to say, we do not know how or whence it comes; but we do know this, that those who have the most of it, those who owed their success entirely to themselves, are the very men who are keenest in the desire that those who come after them should have better opportunities than they had. Look at George Stephenson! No man probably better understood the ideas or the wants of the class from which he sprung; and no man more warmly interested himself in institutions of this kind, as the people of the northern districts well know. His son, Robert Stephenson, was a man of the same stamp; and in that, as in other matters, he followed in his father's footsteps, and I think I am not wrong in saying, unless my memory fails me, that by his will he largely and liberally endowed an institution of this kind in his native town. On that point I should like to call some other eminent witnesses to the truth of what I am saying. Such witnesses would not be wanting, for the name of your late respected president—the name of Fairbairn—will, I believe, be remembered along with that of the two Stephensons. But he is happily present, and I shall allow him to speak for himself. I think that support which such men give to the work we have in hand, is a far stronger argument in its favour than if it were left to the interested assistance of parties or sects, to the patronage of politicians canvassing for popularity, or even to the not illiberal ostentation of millionaires desiring credit for the use they make of their wealth. There is one point in connection with this undertaking which it is always well to notice, I mean your independence of all state aid and of all state control. I fear that in other besides educational matters there is some decrease in that wholesome jealousy, with which the middle classes of England have always been in the habit of looking on any attempt of the executive to extend its functions. I say nothing against the help given to primary instruction, or, in plain English, to boys' and girls' schools. I believe that is necessary. The last generation had, and the present generation still has, to make up long arrears created by centuries of neglect. In such a case, private means would be utterly inadequate; and seeing a great work before it which must be done, and seeing only one means of doing it, the community had practically no option. But I hold that where the necessity ends, there the interference should end also. Freedom, security, industry, will always create large fortunes. Public opinion demands of the owners of wealth that they shall use it

liberally for the general good; and many a man (most men), if I may trust my own experience, would rather give £50 freely, with that reward which they naturally expect from the gratitude of their fellow-citizens, than have £5 screwed out of them by taxes. I don't object to these Government prizes, insignificant as they are in pecuniary value, though I believe if they were done away you would have as much or more contributed by private agency. But I should be sorry to see a system of grants and subsidies applied to adult education, however plausibly such a system might be defended. Even as regards optional inspection, which some people propose (though I don't say there is much harm in it), what can it do for you more than is done already by these various examinations—those of the Society of Arts, and those set on foot by the universities, both new undertakings, and neither costing a shilling to the public? State help has done nothing for English manufactures; English farmers are not trained in Government schools; nor have our great engineers come out of Government workshops. Yet our manufactures travel to every corner of the earth, our engineers are employed in every country, and our farming, imperfect though it may be, is probably the highest in Europe. The work on which you are engaged is only a part, it may be but a small part, of a great national movement. The school, the institute, the cheap newspaper, the cheap book, go together with the benefit society, the savings bank, the freehold cottage, the co-operative mill, and, better still, the co-operative store.—Mr. W. Fairbairn moved a vote of thanks to Lord Stanley, which was seconded by Mr. J. A. Turner, M.P., and carried unanimously, and the meeting separated after passing a vote of thanks to the Chairman.

Fine Arts.

DELACROIX AND FLANDRIN.—The exhibition of the collected works of Eugène Delacroix is about to close shortly. It is now proposed to gather together as many as possible of the paintings and sketches of the late Hippolyte Flandrin, and to exhibit them in the rooms of the *École des Beaux-Arts*. Should this intention be carried out, and there is no reason to suppose that it will not, there is no doubt that a highly interesting collection will be the result, though the best, or some of the best productions of Flandrin's pencil must still be sought in the churches and other public buildings of Paris and other towns; nevertheless, the sketches for those large and elaborate works are, in an artistic point of view, deeply interesting. In the case of the Delacroix sale, this class of works formed by far the most attractive of the whole collection, and the same must be the case, or nearly so, in the instance of Flandrin. The Municipal Council of Paris has, on the proposition of the Prefect, followed the example of the Emperor, and voted the sum of a thousand francs in aid of the funds for the monument of Flandrin, to be placed in the old church of Saint-Germain-des-Prés, which contains so much of his painting. A commemorative tablet, in bronze, has just been placed on the façade of the house in the Place Furstemberg, in Paris, in which Eugène Delacroix died; another is to be affixed to the house at Charenton-Saint Maurice, where he was born.

PUBLIC STATUES.—An equestrian statue of Napoleon I. is about to be raised in the Place d'Armes at Grenoble, to commemorate his passage through that town on his return from Elba. The Emperor is to be represented in the costume which he wore at that period. On the two long sides of the pedestal are to be placed bas-reliefs in bronze; one representing the Emperor at Laffrey, at the moment when, accompanied by a weak escort, and opposed by a troop sent to bar his passage, he is said to have bared his breast and to have cried—"Soldiers, I am your

Emperor! Do you not know me? If anyone desires the life of his general let him take it!" The other bas-relief represents the Emperor outside Grenoble, at the moment when preparations were being made to force the old gate of Rome. The statue is to be in bronze, and placed on a bold pedestal of the fine stone of the Ardèche. Between twenty-five and thirty designs have been sent in for the monument to be erected to the memory of the late Minister Billault, in the town of Nantes; they are to be exhibited this week in the museum there.

PICTURE BY GREZZE.—A dealer in curiosities purchased a picture the other day of a country curé, near Cambrai, for fifteen pence, and sold it almost immediately afterwards for two pounds; after passing through one or more pairs of hands it was purchased eagerly by a rich amateur of Rheims for the sum of 3,100 frs. (£124).

EXHIBITION OF FINE ARTS AT BORDEAUX.—The exposition of the *Société des Amis des Arts* is announced to open in March next. Works intended for exhibition, including paintings, sculpture, architecture, engravings, drawings, and lithography, are to be sent in between the 1st and 10th of February. The society pays all expenses in case of artists invited to contribute, but the size of cases is confined to six feet in height and width; and the weight of sculpture to 400lbs. The present year is the thirteenth of the society's existence, and the exhibition was opened on the 20th of March and closed on the 22nd May. It contained 473 works of art, of which 113 were sold for the aggregate sum of 51,869 frs. The sales of the twelve former years amounted to 539,972 frs. (£21,599). Of these, fifteen works were acquired for the Bordeaux Museum, at a cost of £3,000. This year the Emperor became patron of the society, and contributed a thousand francs to its funds. The Conseil-Général of the Department voted 1,500 frs. and the Municipal Council of Bordeaux 1,000 frs., besides supplying the gallery for the exhibition without charge. The society counts 600 members, who subscribe each a pound a year.

SALES OF OBJECTS OF VERTU IN PARIS.—The collection of the late M. Fossé d'Arcosse was disposed of the other day, and some of the objects realised very large prices. Amongst the most curious was an hour-glass which belonged to Henry II. The frame was supported by five columns in gold and mother-o'-pearl, at each end was a medallion in mother-o'-pearl, one representing the bust of the king, with the letters HR. FR., and the other the arms of France. The hour-glass was enclosed in a case of stamped leather, decorated with gold fleurs-de-lis, and was accompanied by two letters in proof of its authenticity. The whole fetched 2,000 frs. A small lantern, in paper and mother-o'-pearl, ornamented with silver, formerly the property of Marie Antoinette, sold for 89frs. A hammer, which belonged to Louis XVI., an elegant tool, ornamented with incised work, including dolphins and the letter L interlaced, fetched 130 frs. A small gun made for another unfortunate dauphin, Louis XVII., sold for 180 frs. A mother-o'-pearl medallion, bearing a bust of Louis XV., signed Durand, and presented to the king after the battle of Fontenoy, 120 frs. A snuff grater, formerly belonging to the regent, in ivory, ornamented with a subject from the story of Mars and Venus, and bearing the arms of the House of Orleans, 118 frs. A hunting knife, the blade pierced and engraved, and the handle in ivory, decorated with the arms of France and Burgundy, 232 frs. A miniature of the Princess Pauline Borghèse, by Isabey, 163 frs.

CHARLES V. INKSTAND.—A very curious object is now on sale at a shop in Madrid, an inkstand, composed of Egyptian amber, ivory, gold, and carnelian, formerly belonging to Charles V. It is in the form of a Greek temple, of the composite order, decorated in all parts with carving and painting of high finish. In the interior are the arms of the Emperor, surrounded by portraits of all the members of his family. On the sides are figures of an immense number of the grandes of Spain of that period, cardinals, bishops, captains, generals, and beautiful

n. The lid is ornamented with a portrait of Cardinal dea, by the side of which are statues of Diana and . The interior is divided into two compartments; e is a statuette of the Emperor, and in the other of the Empress; and at the foot of these are smaller m, representing Piety and Hope. A figure of Neptune. see coloured carnation, is detached, and its proper tion cannot be determined. In the opinion of good as this curious object represents twenty years' labour.

Manufactures.

SUBMARINE AND OTHER FOUNDATIONS.—An invention Captain Thomas Bridges Heathorn, R.A., of 14, St. men's-square, London, has for its object improvements the construction of submarine and other foundations in p water, under the circumstances of a level, shelving, sloping bottom of a varying density, possibly covered in mud, sand, or shingle to a great depth. The method constructing the foundations for such structures upon a wet bottom is as follows:—The caisson, which is of under construction, with a triangular section, is made of not iron; the bottom portion is floated out to sea, exactly at the spot upon which the building is to be erected, it there anchored; concrete is then placed in the caisson, as to cause it to sink equally, and, as soon as it is fairly deep in the water, an additional height of the m is fixed, and more concrete placed therein to sink deeper. This operation continues until a firm foundation is obtained by the weight of the caisson with its rior filling of concrete causing it to sink through the l or other soft ground to the hard ground beneath; the rior is then filled up with stone or concrete, upon ch, and the concrete in the caisson, the superstructure vted. For shelving or sloping bottoms the caisson bear only upon the highest side of same, and to rve the perpendicular of the said caisson, immediately abee the hard ground, stones are placed in the r of the caisson, which will naturally settle them- in such position as to form a wall underneath that s of the caisson which does not touch the hard l, thereby forming a foundation upon which the may rest. The mode of obtaining foundations in ater will also apply to obtaining same in soft or ground on land, and in some cases the interior of stones will be omitted, and the caisson allowed until it is prevented from further movement by rnal apertures closing, as the building up of the le terminates in a conical apex.

MUSEUM AND LIBRARY OF INDUSTRIAL ART, PARIS.—museum and library has just been commenced by m *Centrale des Beaux-Arts appliqués à l'Industrie*, ve already been referred to in a cursory manner mms of the *Journal*, and which are installed in a mms in one of the houses of the fine old square called e Royale. The collection is not yet very large, but s well. The museum contains some admirable ns of art manufactures, ancient and modern, in- porcelain, faience, terra-cotta, enamels, wood ; fine old tapestry work from Holland, with vidently borrowed from the East; some specimens ook-binding, and a number of illuminations of anty. There are also many interesting objects of laneous character; amongst these are two or three s of a kind of ornamental work that is rather rare, chased bronze; bouquets of flowers and other ts being carved in high relief, apparently in the etal, or possibly cast and afterwards chased. rious plates are of the time of Louis XIV. The contains a large number of fine illustrated works ns kinds, and it was pleasant to read the names of Owen Jones, and other English writers on artistic on several title-pages and backs. The most charac- feature, however, of this department is a large

collection of patterns that have been actually used in the manufacture of ornamental tissues and paper hangings; these occupy a very long range of large portfolios, and are peculiarly adapted for the class of students for whose benefit this establishment is specially designed. There are also some curious collections of old patterns and specimens of actual fabrics, and some paper hangings of the earliest period of that manufacture in France, copied apparently from chintzes which, as regards taste in design, neatness in execution, and brilliancy of colour, would lose nothing by comparison with a very large proportion even of the most beautiful works of that class produced by the able French manufacturers of the present day. A portion of the contents of the museum, and, probably, of the library also, are lent for exhibition by their owners, but the remainder have been purchased out of the funds of the society. It is a remarkable fact, especially in France, that this laudable institution is the result of purely individual exertion, the whole of the members of the committee of organisation, with one single exception, that of a banker, being artists or manufacturers—architecture, designing, mechanism, bronze work, ornamentation; carpet stuff, lace, paper hanging, furniture making, and goldsmiths' work being all represented. These far-seeing industrial artists, warned by the rapid progress made in other countries since the commencement of the era of international exhibitions, formed themselves into a society, with the title given above, in 1861, for the organisation of Exhibitions of Industrial Art, the first of which was held in that year in the Palais de l'Industrie, and the second in 1863, and announces a third, on a much larger scale, for 1865. The Museum and Library are very important results of the Society's action. At present, and till the end of the present month, the new Museum is open to the public, but it is intended for a place of study, not as a popular exhibition, and, being unaided by Government grant or the public purse, the committee will be compelled to charge a fee to the students; this is at present fixed at three francs (half-a-crown) a month. In addition to the use of the Museum and Library, the subscribers will have the benefit of courses of lectures and elucidations, to be given in the evening, by artists and others capable of guiding the students to a due appreciation of the contents of the museum and library, the proceeds to be employed in the augmentation of both. As regards the majority of the articles of modern manufacture, they will be renewed at intervals of three months, so that the young designer and workman will have an opportunity of studying and comparing the products of the present day as they appear. In speaking of the new Institution the other day, a Parisian journalist said:—"The Museum of South Kensington, the honour of England, had a more modest commencement than this." This is scarcely the fact, but the observation shows how the efforts made in our country in the direction of Industrial Art are appreciated abroad. This Society, although self-formed and self-supporting, has the countenance of the authorities; the museum has been visited by the Minister and Superintendent of Fine Arts, and the former has presented it with an admirable collection of sea weeds, arranged by an artist-designer, who presented it to the Emperor, in which the natural specimens are accompanied by samples of tissues, the designs for which have been derived from the types here brought into direct comparison with them. The courtiers of the Court of Catherine de Medicis, who once inhabited this fine quaint old square, little thought that a Working Man's Museum and Library would one day occupy the best floor of one of their courtly mansions.

LARGE TELESCOPES.—A fine reflecting telescope has just been sent from Paris to the Marseilles observatory; this instrument measures eighty centimètres, or 31·520 inches aperture; its focal length is five metres, or 5·477 yards; and it is moved by isochronate machinery. It is the work of M. Léon Foucault. The Toulouse observatory is having one constructed on still larger proportions.

Colonies.

AUSTRALIAN DIAMONDS.—Diamonds have from time to time been found in the Ovens district, Victoria. Two were recently found by a man named M'Gill, in Finn's claim, on the Woolshed. One of these is said to be worth about £8 in its present state. These make seven diamonds found in the same claim. There has never yet been any systematic search in the district for precious stones.

THE SALMON EXPERIMENT.—We have to record an important event in the progress of the great salmon experiment. The parr artificially reared in Melbourne have been successfully deposited in a suitable stream. Mr. Ramsbottom, who brought the ova from England, reported to the Acclimatisation Society that the Yarra was admirably adapted for a salmon river—the more especially as better tributaries than the Watts and the Badger could not be wished for. The Council of the Society, remembering that the coming warm weather would greatly increase the difficulties of removing the fish, and being of opinion that it was of the greatest importance that the breeding depot should be within an easy distance of Melbourne, resolved not to detain Mr. Ramsbottom in exploring the Gipps Land and the other rivers which had been suggested as adapted for the purpose, but to authorise him to remove the parr to the Yarra with all possible speed. The particular spot which was selected is a point of the Badger Creek, about forty-five miles from Melbourne. Here a tank has been constructed, twenty-one feet long, six feet wide, and from two-and-a-half to four feet deep, the variation being intended to suit the fancies of the young fish for shallow or deep water. Through this tank a stream from the creek is made to run, and in it the parr will remain until, having developed into smolts, they are ready for sea, a date at least twelve months distant. The task of removing the parr was a very delicate one. The little fish were skillfully got together, and introduced to a travelling tank, which was swung from an improved universal joint in a light American waggon, while, so that the parr should not feel the change from a running stream, Mr. Ramsbottom sat by the tank throughout the journey aerating the water by dipping out cupfuls and pouring them back again. Leaving Melbourne at half-past three o'clock in the morning, the juvenile strangers reached their destination at half-past three the same afternoon; and, thanks to Mr. Ramsbottom's assiduity and to the skilful driving of the coach, only nine deaths occurred during the rough and long way. It is to be regretted that upon the parr being removed their number was found to be far less than it was supposed we were possessed of. Still, there is every reason to hope that there are enough in the Badger to secure the return of some of the grilse from the sea, and thus to render certain the success of the experiment. Thus far the work has gone on favourably. The past gives us confidence that in the end success will be attained. From Tasmania we hear good accounts of the parr deposited in the breeding ponds at Derwent; they are progressing favourably, but there will be no change to report until the advent of that mysterious instinct which prompts them seawards.—*Melbourne Argus*.

GRANITE.—A gigantic block of granite, thirty-six tons in weight, has been brought down to Melbourne from Harcourt (Victoria), in order to be worked into a monument, intended for erection over the remains of the explorers, Burke and Wills, in the Melbourne General Cemetery.

POST OFFICE SERVICE (VICTORIA).—The Victorian Government have proposed to establish a fortnightly service, in connection with the Peninsular and Oriental Company, at a cost of £50,000, one moiety of which they requested might be contributed by the colony. The New South Wales Government have, however, declined to co-operate with the Victorian Government in the establishment of the fortnightly service referred to. It still charges double

postage for all letters sent to the United Kingdom by the mail steamers, notwithstanding the increased postage has been suspended in England. This step has caused much dissatisfaction, and has induced many persons who have a large correspondence to forward their letters to Melbourne for transmission. The other colonies continue to charge the old rate.

COAL IN NEW ZEALAND.—The Provincial Government is exerting itself to promote the working of the West Coast coal fields; and two tons of coal from the Buller, and about twenty-five tons from the Grey, are now in Nelson, being got ready for shipment to London for the purpose of being tried and reported upon by the Board of Admiralty. Meantime, boring on the side of Mount Rochfort, near the mouth of the Buller River, is being carried on with a view of ascertaining whether, by a drive or a shaft, the coal can be got on that side of the mountain instead of at the back, where it crops out in thick seams. If the results be favourable a great saving in the cost of constructing a road from the coal to the mouth of the river will be effected. The coal from the Grey is highly bituminous and burns strongly; that from the Buller is a harder coal, and is supposed to be the best for the furnace. Boring for coal is also going on at Pakawau. We stated some time ago that at a depth of fifty feet an excellent seam four feet in thickness had been discovered, but the boring has been continued, and has now reached a depth of 98 feet. The parties interested are sanguine, from the indications of the strata, that they are approaching other seams of equal, perhaps greater, thickness than the one spoken of.

Obituary.

CHARLES HARRIOTT SMITH, an old member of the Society, died on the 21st of last October. He was born on the 1st of February, 1792. His father, a respectable stone mason, in the Portland-road, considering reading, writing, and arithmetic, as sufficient scholastic acquirements for his business, took his son from school at the early age of twelve years, to initiate him in the operations and technicalities of stone masonry; but he soon acquired a taste for the conversation of well-informed persons, some of whom, especially Mr. Bonomi, the father, and his friend, young Donaldson, encouraged his aspirations for higher pursuits. After working hours, he employed himself in drawing and modelling. This paved the way to his admission, as a student, to the Royal Academy, where, besides modelling and drawing, he applied his mind to the study of Grecian and Gothic Architecture. He became a member of the Society of Arts in 1814, when he was only sixteen years of age. If at the Royal Academy he acquired skill in the practice of his art, here he learned to reason and collect information. With what satisfaction, in after life, he would dwell on the discussions of Alexander Galloway, Bryant, Donkin, Brunell, and other able men, from which he derived much mechanical knowledge; from Britton, Brayley, and Strutt, he acquired a taste for archaeological research; and in chemistry, mineralogy, and geology, he found valuable instructors among its members. Soon after his admission, the Duke of Northumberland, presiding, put a subject to the vote; seeing a youth of sixteen hold up his hand, his Grace asked if boys were allowed to vote; the answer was in the affirmative, and young Smith, proud of the privilege, was the more anxious to exercise it discreetly and honourably. He soon secured the good-will and growing esteem of many of the members, as Charles Warren, Horsman Solly, Britton, Varley, Brockedon, and of their excellent Secretary, Mr. Arthur Aikin. When the late Sir Charles, then Mr. Barry, was preparing to carry out his designs for the Parliament Houses, he felt a difficulty in obtaining an adequate supply of good stone, and proposed to Govern-

sent a survey of all the principal quarries in England and Scotland; fortunately, he became acquainted with Smith, through the late Joseph Hume, one of the Vice-Presidents of the Society of Arts; and the Royal Commission for this inquiry was composed of Mr. Barry, Sir Henry De la Beche, the well-known geologist Dr. William Smith, and the subject of this notice. Their examination of our ancient buildings, castles, and churches, and of the quarries whence the material had been drawn, was careful and judicious, and the report proved a valuable addition to our artist's professional knowledge. Mr. Smith's zeal and intelligence had won for him the esteem of his fellow-commissioners, and their friendship continued through life. Sir Charles Barry, having decided on the quarry that from experience, and from tests carefully made by Professors Daniel and Wheatstone, was best suited for his purpose; but aware that in every layer there are imperfect veins, proposed to Government to appoint Mr. Smith inspector of the stone as supplied by the contractors, in order that his practical knowledge should prevent any unsound admixture; unfortunately, false economy prevailed, the precaution was not adopted, and many inferior blocks were admitted, to the serious regret of all parties. Mr. Smith's sound knowledge was generally recognized: he was elected an honorary member of the Royal Institute of British Architects, to whose transactions he contributed many interesting papers. In later times he visited the quarries of Caen, in Normandy, in company with Mr. George Godwin, F.R.S., the interesting results of which soon after appeared in the *Builder*. He had become a sound authority on the subject, and all who had, or thought they had, a bed of valuable stone in their estate applied to him for his opinion, which he gave most liberally and honestly, too much so, perhaps, to agree with many ill-founded expectations, however candid and kind. As a writer and a lecturer he was clear and distinct; occasionally, but not often, a touch of humour or of ornament glittered for a moment. Some of his best writing is, perhaps, an essay on "Linear and Aerial Perspective," in Arnott's "Library of the Fine Arts;" an excellent treatise on an important subject of which he was thorough master, and which gave him a skilful and judicious execution of ornaments at the London University, the Royal Exchange, and other buildings. At the Royal Academy he gained the gold medal for the original architectural designs in 1817, and continued for successive years to exhibit designs in architecture and models, and portrait busts and monumental compositions; but science, chemistry, geology, antiquities, and general knowledge, led him chiefly to scientific institutions, where his conversation was always acceptable. The year before his death, though suffering, he visited the Isle of Mull and Iona, and returned an enthusiastic admirer of the Scottish Royal monuments; but increasing infirmities prevented him from writing an account of them, for which his peculiar talents and knowledge so admirably fitted him.

FREDERIC STRUVE.—The celebrated Russian astronomer, whose name is associated with all the great works of triangulation and geodesy carried out in Russia and Eastern Europe, died on the 23rd of November, at St. Petersburg. He was born at Altona, in April, 1793, and studied philology, and afterwards astronomy, in the University of Dorpat, in the government of Livonia. In 1813 he was attached to the observatory of that town, becoming its director four years afterwards. In 1832 he removed to Pulkowa, and was appointed director of the magnificent observatory which the Russian Government had established there, which post he retained till his death. Mr. Struve undertook and carried out various important works and scientific expeditions, by a description of which scientific libraries are much enriched. His son, M. Otto Struve, died under his accomplished father, and obtained the post of Second Astronomer of the Pulkowa Observatory. **PROFESSOR BENJAMIN SILLIMAN, sen.**, expired at his residence, New Haven, U.S., on the 24th Nov. Mr. Silliman

was the son of Gen. Gold Selleck Silliman, who rendered his country important service during the revolutionary war. He graduated at Yale in 1798, afterwards studied law, and was admitted to the bar in 1802. He afterwards accepted the chair of chemistry in Yale College, and visited Europe to prosecute his studies in a science which was at that time almost unknown in America. He returned after an absence of fourteen months, and published an interesting account of his travels. In 1807 he made a chemical analysis of a meteorite of great size and brilliancy which had burst in the town of Western, Connecticut. He afterwards assisted Dr. Ware in his experiments with the oxyhydrogen blowpipe, to which he gave the name of "compound blowpipe," by which it is commonly known. In 1818 Professor Silliman founded the *American Journal of Science and Arts*, better known both in Europe and America as *Silliman's Journal*, of which he remained senior editor till 1846. He was one of the earliest Americans to give popular lectures on scientific subjects. In 1830 he visited Europe a second time. He resigned his professorship in 1853, but continued to give lectures for two years longer. He was a man of simple tastes and active habits, and his old age was remarkably free from mental or bodily infirmity, and to the very last he took a deep interest in the progress of science, humanity, and freedom all over the world.

Publications Issued.

L'ARCHITECTURE PRIVEE AU XIXME. SIECLE SOUS NAPOLEON III., &c. Par M. César Daly. Folio. Paris: Morel and Cie.—The author of this work is well-known as one of the most daring and elegant writers on architecture in France, and yet, with the experience of what he has done before, the present publication is a marvel, and does high honour to the reign in which it is produced. It consists of three folios of engravings, in all about two hundred plates, executed on steel, in the most careful and artistic manner, representing select specimens of the architecture of the present day in France, divided under the three main heads of private houses or hôtels, houses constructed for being let out in separate tenements, as is usual in Paris, and villas or suburban residences. Each example is accompanied by plans and details, covering, in some instances, ten or twelve sheets, and each of the nine groups or sub-divisions is accompanied by what is called a parallel of plans, or, in other words, a collection of plans of other houses of the same class brought into comparison with each other. The elevations are drawn to a scale of one in a hundred, and the plans half that proportion, while the smaller details are given on one in four. It is impossible to exaggerate the beauty of the work in an artistic point of view. Every line is as clear as print, yet each elevation is a picture, but without anything extraneous being introduced. The cleverness of French architectural draftsmen is well known, and no work that we are acquainted with affords better examples of it than that under notice. It is a monument of drawing and engraving as well as of architecture. The letter-press which prefaces the work contains a good deal of matter of interest to others besides architects. M. Daly makes judicious remarks on the essential differences between public and private architecture, on the requirements of families with respect to accommodation and health, and on the peculiar demands arising out of French habits and manners, which he contrasts with those of England, a task for which he is peculiarly fitted, as having passed a considerable portion of his life in this country. Secondly, he treats the important question of the proper characteristics of art as applied to private dwellings, and where they differ from those which should mark the public edifices of a city. Thirdly, he sets forth a series of canons of construction, both as regards single and compound edifices;

and, lastly, he gives an elaborate estimate of the cost of the new houses in Paris and its environs, in all their details. The résumé of this portion gives us the following information:—Private mansions in Paris, of the first and second class, cost, on an average, from 500 to 650 francs per mètre superficial, and those of the third class 400 to 450 francs; mixed residences in Paris, from 500 to 1,100 francs; and suburban residences from 400 to 600 francs. M. Daly boldly dedicates his work to Baron Haussmann, the prefect of the Seine, whom Paris wits call the Arch Destroyer, but whom M. Cesar Daly, and, probably, architects in general, regard as a special providence.

L'ETRURIE ET LES ETRUSQUES. Par Noel des Vergers. 2 vols. and Atlas. Paris: Firmin Didot.—This is the work of a learned and a travelled man, an original and important production. The first volume is devoted to the geology of Etruria, the origin of the Etruscans, their confederation in the plains of the Po, their commercial relations with the nations of Greece and Italy, their political constitution, their religious systems, and the development of the arts amongst them; the second volume traces the history of the nation from the foundation of Rome to the end of the Empire. The "Atlas" contains chromo-lithographic representations, beautifully executed, of the best known types of Etruscan vases, and each plate is accompanied by a commentary, in which the difficulties that surround the interpretation of the mythological figures and emblems of the period are discussed and explained. In addition to this the author has given a collection of epigraphic monuments, a comparative table of the Etruscan, Phœnician, and Greek archaic alphabets; and an archaeological chart of Central Etruria.

WORKS OF THE ETCHING SOCIETY OF PARIS.—The Société des Aquafortistes, now three years old, exhibits great activity and much talent, although some times a little eccentric, wanting rather in a nice appreciation of the line of demarcation between the comic and caricature. Amongst its recent productions is a graphical edition of the famous old legend of Marlborough, "Malbrook," full of riotous fun and sparkling with invention, an admirable example of the grotesque; the artist being M. A. de Boret. Another series of a very different kind, by M. C. Longueville, consisting of twelve plates of landscapes and marine pieces, exhibits a fine eye for effect and most careful execution. The young artists of Paris have taken up etching as a weapon against wood engravers and photographers, and they are perfectly right in so doing; the conflict cannot but be good for art, and none of the combatants are likely to suffer.

REPORT ON VARIOUS HOSPITALS OF GENEVA, TURIN, AND MILAN. By Anthony Roulliet. This is a document addressed to the French Minister of the Interior, and is an instalment of the information which is being collected by a commission appointed by imperial decree, to inquire into the alimentary and sanitary systems of hospitals. The inquiry is intended to embrace all the hospitals of Paris and London, and also those of several other towns in France and other countries. The returns obtained from the French hospitals, with the aid of the authorities, are said to contain much important information; as regards London, it is said that nothing has yet been done. The author of the report in question is an advocate, attached to the commission, and was charged to collect information in Italy and Switzerland. The report is general in its scope, and includes, amongst other things, plans of the buildings, apparatus for ventilation, systems of washing, cleansing, baths, medical and pharmaceutical services, and tables of mortality.

FABRICATION DES ETOFFES. TRAITE COMPLET DE LA FILATURE DU COTON. Par M. Alcan. Paris. This is an important work, in two parts, on the spinning and weaving of cotton and other textile fibres. The first part contains an investigation into the peculiarities of the fibres themselves, illustrated by microscopic sections; the cotton of

Egypt, India, the Levant, and Algeria, and the proposed substitutes for that fibre, being especially considered. It includes also a history of the progress of the industry from the earliest known period. The second part is more specially technical, and includes a curious synoptical table of the transformations of fibrous substances, such as cotton, flax, hemp, wool, and silk. India rubber, the metals, glass, and bark, which are employed, or might be employed, as auxiliaries in textile manufacture; elaborate descriptions of machinery used; and a chapter on the establishment of mills, their construction, lighting, heating, ventilation, steam power, and cost. The work is illustrated by fifty plates and cuts.

WORKS OF ALPHONSE X., OF CASTILE.—The third volume of the works of this old astronomer has just been presented to the Paris Academy by M. Le Verrier, who calls attention to the curious fact that the path of the planet Mercury is there described as oval. Alphonse wrote in the eleventh century, and of course knew nothing of the laws of Kepler, but he had arrived at the conclusion that nothing but a kind of ellipse would represent the movement of Mercury.

Notes.

EDUCATION OF GARDENERS.—The Royal Horticultural Society has just issued its programme for the ensuing year; and members of the Society of Arts will see with satisfaction the announcement made respecting the education of gardeners, as follows:—"Examinations and Certificates for Gardeners.—Central Examinations of Gardeners in Theoretical and Practical Gardening will be held annually at South Kensington, and Local Examinations will be held in the country. Certificates of competency and prizes will be awarded at both Examinations."

A CHIMNEY, about 100 feet high, comprising about 90,000 bricks, and estimated to weigh over 200 tons, was recently moved a distance of 100 feet in Worcester, Massachusetts, without breaking a brick.

RAILWAY IN BRAZIL.—A new railway has recently been opened in Brazil, which crosses the mountain chain. Serra-do-Mar, and connects the interior fertile plains with the sea-coast. It is eighty-eight miles long, and attains, in the course of five miles of mountain-steep, an elevation of 2,600 feet. The entire ascent is divided into four lifts, or inclines, of a mile and a quarter each, running at a gradient of one in ten. A level platform, or "bank-head," marks the summit of each incline, and at the upper end of the platform is a stationary engine. This engine has double cylinders of twenty-six inches diameter, with a five-foot stroke, and has been calculated to haul up fifty tons at the rate of ten miles per hour. Five boilers, of the Cornish description, are placed with each engine. On the upper half of each incline there is a double line of rails, with arrangements for passing-places on the middle of each of these lifts. A single line of rails then run on from the centre to the foot of each of the four divisions into which the ascent is divided. A steel wire rope, 1½ in. diameter, is made for pulling up the ascending trains. This rope, tested to a weight far exceeding the requirements that will be made upon it, passes over friction-wheels, and is attached to the fly-wheel shaft. The inclines are partially self-acting, at the same time passing one train down to the foot of the Serra and drawing up another to the higher levels on its way out to the province beyond.

A LOCOMOTIVE from Spain has passed through the Pyrenées into France, along the new series of tunnels, about forty miles in length. This was merely a trial trip, and it was perfectly successful.

RAILWAY BRAKE.—An experiment was lately tried to ascertain how quick a railway train under full headway might be stopped. It was allowed to attain a speed of fifty miles an hour, when the brakes were applied and the steam shut off. It came to a dead stand after running about 500 yards, being 60 yards more than a quarter of a mile.

SUBSTITUTES FOR CRANES AND HODMEN IN PARIS.—The *Builder* states, that "some of the contractors rebuilding the demolished houses, and running up quickly new mansions, have hit upon an ingenious way of raising materials to the top of the scaffold. As the head of water at the Villette is enough to command any of the houses in Paris, they have simply a pipe turned on from the main up to the top of the intended structure, and by that means can fill a bucket or large tub, which in descending draws up a plateau on which the materials are placed. The water, being turned into mortar, and otherwise made use of afterwards below, is not lost. Some of the materials are also hoisted by Lenoir's machine (by gas); there is one at work at the Rond Pont de Corcelles, close to the Avenue de Ternes. It seems to be, by timing a weight ascending a certain height, about 2½-horse power. The absence of a boiler in these engines is a strong argument in favour of employing them where steady slight power is required. At all events, if they are not endowed with the abundant force of a steam-engine, yet in towns and confined streets, where only a moderate source of power is required to act in a small compass, noiselessly and without nuisance, we have seen that the required mechanical effect can be accomplished without risk of explosion, and consequent damage and loss of life, either to owners or their neighbours. That is something, at all events."

TECHNICAL EDUCATION IN FRANCE.—The *Société Polytechnique*, for the gratuitous instruction of workmen, is of some years' standing, and has branches in all parts of the capital. The other day there was a meeting of the Surveys section, when M. Glachant, the Chief Secretary of the Minister of Public Instruction, presided, and made a remarkable speech. This gentleman has evidently studied the subject—technical education—both at home and abroad; he told the assembly that reading, writing, and arithmetic, were not learning, but merely means for acquiring education, and that the present state of society demanded for the workman a knowledge of the principles of his art, without which he ran great danger of becoming a mere slave of mechanism, the machine which he should direct. The remarks concerning what had been done abroad showed how carefully France watches what is going on elsewhere. In Belgium, said M. Glachant, with a population of four millions, there are no less than 1,145 adult schools, of which 27 meet in the day-time, 173 in the evening, and 945 on Sunday, the total number of scholars being 180,000. At Ghent there are more than 40,000 weavers, and not a single industrial school—the evening schools supply all that is wanted. In Russia education is obligatory until the age of sixteen; after that the youths attend the schools of Art and Industry (*Gewerbeschulen*). The Sunday schools of Barmen and Eberfeld were established by a generous Frenchman, but the authorities of the latter place aided with a vote of 600,000 francs (£24,000). But the example of England occupied the greater part of M. Glachant's attention, not only on account of the amount of effort made, but also for the originality of the form as regards the Literary, Scientific, and Mechanics' Institutions, which are certainly unique in Europe. The influence of these is illustrated by the fact of "700,000 francs being raised for some special object by voluntary subscription in one day at the Manchester Mechanics' Institution, and by the act of the Society of Arts in obtaining the guarantee for the Exhibition of 1862. M. Glachant applauds the system of the introduction of music and other means of recreation into our popular institutions, and says:—"As our neighbours

have borrowed the word *Soirée* from us, let us borrow from them the thing to which they have applied it." But it is the Kensington Museum which calls forth M. Glachant's warmest encomiums. He calls it the "Babylonian museum of South Kensington." He gives the statistics of the schools there and in connection with it; he speaks of the acts of the Committee of Council of Education as "the most gigantic effort ever made in aid of industrial art and the generalization of practical instruction." "On the morrow of the Exhibition of 1862," he says, "a cry of alarm arose amongst our workmen (the French) that England had moved!" His concluding remarks are for all the world:—"Pupils of the Polytechnic Association, it is not necessary to show you that your rivals are doing their best to cause you to exert yourselves. You will soon learn, if you have not already, all the secrets of your professions. On this head you might teach your professors. Still you will listen to those men who have never handled a tool, for you know that they can aid you in becoming more expert; for increased intelligence gives the hand more hardihood and dexterity. An ignorant workman dare not depart from an old bad system; but he who has learnt to reflect searches and finds improvements and new applications, which often produce revolutions in industry."

FINAL DEMOLITION OF THE EXHIBITION BUILDING.—On the 12th instant, at half-past eleven, the whole of the central entrance in the Cromwell-road was brought to the ground, being the last appearance of any part of the Exhibition building. The public will recollect what an enormous mass of brick-work this was. Some of the piers were twelve feet in thickness. Having been prepared beforehand, by the sappers, under command of Lieut. Knocker, a hundred-and-twenty-pounds of gunpowder in as many separate charges, distributed at the footings of the whole mass, were fired simultaneously by two electric batteries. The charges had been so arranged, and the calculations so made, as to cause the whole mass to fall inwards towards the north; and the mass was obedient to the laws of science, so that not a brick tumbled in the Cromwell-road. The greater part of the northern side gradually subsided to the ground, leaving momentarily a large portion, which was projected inwards, by the fall of the Cromwell-road front upon it. As soon as the smoke and dust had cleared away the western tower was seen to be standing. Gradually the sappers approached to find out why it had not fallen like the rest. They had scarcely reached it before it began to vibrate, and in a second afterwards fell like the other portions. Each part of the towers and great arches of the Exhibition building have thus afforded a series of the most valuable experiments, and it is said that the data obtained considerably modified those which formerly were accepted. The experiments have lasted about three months, and the delay, which some persons did not understand and complained of, is now fully explained by the successful work of last Monday. The members of the Society of Arts will be glad to be informed that a paper on the subject, by Lieut. Knocker, will be read in the course of the session.

CONSUMPTION OF SUGAR IN ENGLAND AND FRANCE.—Official documents show that the consumption of sugar in 1863 in England and France was as follows:—England, 480,000 tons; France, 260,000. The average consumption for the four years—1846 to 1850—was respectively 280,000 and 112,000 tons, and for the four years—1850 to 1854—357,000 and 119,000 tons. The consumption has consequently doubled within 18 years—a fact of some importance, the consumption of sugar being held a conclusive test of material prosperity.

CANADIAN journals are agitating the subject of a grand Provincial Exhibition, in which the two Canadas shall unite in offering 20,000 dols. in premiums, and challenging New York State to enter the lists in competition therefore. It proposes, as an inducement for exhibitors from long distances, that premiums be offered for leading products

of the manufacturing and agricultural interests only, so that they would tempt a large competition. It is asserted that leading agriculturists of Lower Canada are anxious to bring about such a joint exhibition.

MEETINGS FOR THE ENSUING WEEK.

- MON. ...** Society of Arts, 8. Cantor Lectures. Mr. B. Waterhouse Hawkins, "On the Reproduction of Natural Forms by Art and Manufacture." Lecture II.
British Architects, 8.
Medical, 8. Mr. Hunt, "On the Present State of Medical Logic."
R. Asiatic, 3.
TUES. ... Civil Engineers, 8. Annual General Meeting.
Statistical, 8. Mr. James Heywood, "On the Extension of Modern Subjects as a part of Regular Study in Educational Institutions."
Pathological, 8.
Anthropological, 8.
WED. ... Society of Arts, 8. The Articles sent in Competition for the Art-Workmanship Prizes will be Exhibited, and a Report in connection therewith will be read.
Geological, 8. 1. Mr. W. Keene, "On the Coal-measures of New South Wales with *Spirifers*, *Glossopteris*, and *Lepidodendron*." Communicated by the Assistant-Secretary.
2. Mr. Searies V. Wood, jun., "On the Drift of the East of England, and its Divisions."
London Institution, 7.

Philosophical Club, 6.

Patents.

From Commissioners of Patents Journal, December 9th.

GRANTS OF PROVISIONAL PROTECTION.

- Butts of bent iron plates, machining the ends of—2900—T. W. Penton and H. Penton.
Carbonizing wood, apparatus for—2884—M. Henry.
Cash samples, bags for containing—2910—G. Kottgen.
Cigar holders, butt-pieces for—2928—A. Oberdoerffer.
Coal, &c. machinery for getting—2929—F. Haggie and A. Gledhill.
Coal, distillation of—2484—J. G. Beckton.
Colours, apparatus for stamping—2911—H. L. Maquet.
Colouring matter, manufacture of—2916—J. C. L. Durand.
Engine, rotary—2751—W. Thrift.
Fire arms, breech loading—2951—C. Reeves.
Fire arms, breech loading—2983—W. J. Matthews.
Gold leaf, &c., manufacture of—2872—J. H. Johnson.
Guns, working of—2882—T. A. Blakely.
Hats, manufacture of—2887—W. Wilson.
Hats—2971—A. I. L. Gordon.
Hauling apparatus—2961—G. Newsum.
Heating rooms, boilers for—2828—T. Jones.
Heating apartments, fire-places for—2901—W. E. Newton.
Heating rooms or buildings, apparatus for—2949—J. Grundy.
Horse hoes, &c., construction of—2881—W. Sargent.
Iron tubes, manufacture of—2877—J. Fisher.
Iron and steel, apparatus for manufacture of—2904—J. Griffiths.
Jacquard cylinders, Improvements in—2866—J. Hughes.
Knitted or looped fabrics, machinery for—2886—J. Webster and J. Langham.
Lace, manufacture of—2302—S. Bates.
Lamp—1902—A. Kistemann.
Liquors, apparatus for drawing off—2880—J. Behrends.
Mathematical instruments—2895—J. Pitman.
Motive power—2779—G. A. Galloway.
Motive power—2989—A. Hawkes.
Moulding and planing wood, machinery for—2875—H. Wilson.
Mules for spinning—2922—J. Paley.
Navigable vessels, motive power for—2890—E. S. Jones.
Paper pulp, apparatus for manufacture of—2896—J. Easton, jun.
Paper hangings, gold, apparatus for manufacture of—2903—J. Wylie.
Paraffin, &c., lamps—2871—T. Rowatt.
Paraffin oil, apparatus for drawing off—2981—R. F. Dale.
Photographic processes—2953—L. Crozat.
Piled fabrics, method of weaving—2908—H. Eckeraley.
Pipes and tobacco, cases for carrying—2898—W. Palmer, jun.
Power engine—2918—T. M. Brisbane.
Presses for baling—2578—W. Clark.
Preserving ships bottoms—2985—H. Caunter.
Pressing and baling goods, machinery for—2979—A. V. Newton.
Projectiles, manufacture of—2953—J. P. Nolan.
Pulp, preparation of—2913—W. Ibbotson.
Railway trains, communication between passengers, guard, and drivers of—2935—R. Whible.
Railway trains, communication for travellers with the guard—2868—R. W. Slavier.
Revolvers—2513—J. Williams.
Roads, sweeping, machines for—2975—G. Davis.

- Rock and stone, machinery for excavating—2914—P. E. Gay.
Sails, reefing and furling—2915—T. Shorley and G. Gibson.
Sewing machines—2902—W. Martin.
Sewing machines, winders for—2903—H. Willis.
Ships' anchors—2878—S. Sharp.
Signals—2710—R. C. Robinson.
Signals, &c., apparatus to exhibit—2926—J. S. Gisborne.
Sleepers for railways, machinery for sawing—2874—H. Wilson.
Smoothing and polishing, apparatus for—2930—G. Brunton.
Spirituous liquors, distilling and purifying—2973—C. J. Falkman.
Steam boilers, prevention of accidents with—2891—J. Phillips.
Steam boilers or generators—2893—A. H. Stott.
Steam hammers, &c.—2917—R. Morrison.
Steam in steam engines, regulating the flow of—2888—J. Petrie.
Steel castings, manufacture of—T. E. Vickers.
Studs, buttons, &c.—2956—L. A. Waldemar.
Sugar, manufacture of—2906—A. V. Newton.
Sugar, turbine for drying—2965—L. Montalgué.
Torpedo rams—2799—G. A. Henty.
Travelling railways—2931—E. Molyneux, jun.
Vapour, cold, apparatus for creating—2889—S. Pisse.
Vent pegs and valves—2905—S. Bourne.
Washing, &c., apparatus for—2919—N. Hodgson.
Weaving, looms for—2897—J. Gaukröger.
Weaving, looms for—2956—C. Hartley.
Weaving, looms for—2991—R. L. Hattersley.
Window sashes, apparatus for lifting—2924—S. Price.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

- Gas, illuminating, manufacture of—3042—G. T. Bousfield.
Infant tender and exercising apparatus—3019—G. Haseltine.

CANTOR LECTURES.

THE REPRODUCTION OF NATURAL FORMS BY ART MANUFACTURE." By B. WATERHOUSE HAWKINS, F.G.S., F.L.S.

16TH, 1865.—LECTURE III.—On the varieties of treatment of the forms of animal and vegetable material representation; conventional ornamental, real, and symbolic combinations of animal forms.

23RD.—LECTURE IV.—On the fitness of designs, and adaptation to the conditions of the materials in which they are to be produced. (Demonstrated by metal-processes, sand-moulding, casting, and chasing).

30TH.—LECTURE V.—On Ceramic Manufactures, the Influence of the material on the design and its useful production—modern Terra Cotta, Della Robbia Majolica, and Parian.

These Lectures are open to Members free of charge, and a Member has the privilege of bringing ONE Friend to each Lecture. A ticket for this purpose has been sent to every member.

ART-WORKMANSHIP PRIZES.

Articles sent in competition for the Art-Workmanship Prizes are now arranged for display in the Society's Great Room, and the Members of the Society, as well as Art-Workmen, are invited to inspect them on and after Monday the 26th instant, between the hours of 10 to 12. To suit the convenience of Artizans, it is the intention of the Council to open the rooms several evenings, the dates of which will be notified as soon as arranged.

Proceedings of the Society.

CANTOR LECTURES.

SECOND LECTURE.—MONDAY, DEC. 19.

Mr. HAWKINS first mentioned the fact, that though the union of art and manufactures had been termed by the artist and lecturer Hayden, an "unholy alliance," it is not so in reality, but it is a natural and necessary union, only rendered "unholy" by the war between designer and manufacturer, which is caused by the ignorance on the part of the artist of the inevitable conditions of the material in which his work is to be produced, and the process by which it is to be multiplied, multiplication being the means by which objects of art are put within the reach of the public. Mr. Hawkins then called attention to a shield, lent by Messrs. Elkington, the original price of which was £500, but which, by the happy co-operation of artist and manufacturer, has been multiplied so successfully that it is now offered to the public at less than £20.

Having continued his argument on the subject of art education, Mr. Hawkins proceeded to illustrate his assertion, that a knowledge of the structure of the object which he had to represent was necessary to the artist, by showing, that if the Board of Trade were to employ an artist to represent the positions of a locomotive engine whenever accidents occurred, the first requisite for such a person would be that he should possess a thorough knowledge of the structure of a locomotive engine; and if this were necessary, how much more necessary would it be that an artist, wishing to represent an animal, should possess a knowledge of the structure of animals, which are so much more varied in their attitudes than any steam engine could be even under the most peculiar circumstances of an accident. The lecturer compared the furnace of an engine to the stomach of animals, the heat and blood to the steam, and the cylinder and valve to the lungs, thus showing a parallel for three of the great elements of the animal structure; but he further pointed out that there is in the living being a fourth element, namely, the will, represented by the brain, and conveyed over the whole body by cords which might be compared

to the electric telegraph. This fourth element, being unrepresented in the machine, has to be supplied by a man, who acts as brain to the steam engine, controlling its force, and bringing it into subjection for his own uses. Having sketched on his black canvases a locomotive engine, and the internal structure of a vertebrate animal. Mr. Hawkins observed that this plan of structure is the one plan upon which all vertebrate animals, from the creation even until now have been constructed, the Creator's first design being so perfect as to have been susceptible of every modification necessary to the varied conditions of life on the earth, and in the air and water. By the alteration of a few chalk lines, Mr. Hawkins converted his sketch of a fish into a seal, and from a seal to a deer. He also observed that the unity of plan in animal forms is a great advantage to the artist, so that when he has thoroughly mastered the structure of a typical vertebrate animal, it becomes a comparatively easy task for him to acquaint himself with its various modifications. It is not enough that a draughtsman should imitate the appearance of an animal when he can get one to stand still for him; it is necessary that the designer should be able to represent animal forms in any of the varied attitudes which they may assume without their being present to his corporeal eyes, and this he can only do by being thoroughly acquainted with their structure, with the space occupied by the various parts, and the proportion which they bear to one another. By the system now adopted in art schools the hand of the artist only is educated, and his work is therefore merely imitation, not representation. If the mind of the artist be educated he will possess efficient power to control the movements of his hand, which is made by God to express man's will; and even when the right hand is injured the mind of man has efficient power over the left to compel it to express his will with equal accuracy. By spending his energies in acquiring mere power of handling, the artist neglects his mind; his inventive faculties are not developed; and, instead of enhancing the value of manufactures, which is the true province of decorative art, it is, by this fault in education, lowered in its character, and art thus becomes an enemy to manufactures.

SIXTH ORDINARY MEETING.

Wednesday, December 21st, 1864; William Hawes, Esq., Chairman of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Haines, Alfred, Kensal-house, Harrow-road, W.
Knowles, S., Tottington, near Bury, Lancashire.
Mayson, J. S., Charlotte-street, Manchester.
Peacock, Edmund, 18, Holford-square, Pentonville, W.C.
Tremlett, Rev. Francis W., LL.D., the Parsonage, Belsize-park, N.W.
Whitehead, J. B., Rawtenstall, Lancashire.

The following candidates were balloted for and duly elected members of the Society:—

Abel, Charles Denton, 20, Southampton-buildings, W.C.
Brinsmead, Henry, 12, Rathbone-place, W.
Sharp, Philip Henry, 18, East-parade, Leeds.
Simonds, Professor James B., Royal Veterinary College, Camden-town, N.W.
Simpson, J. Hawkins, 40, Bedford-place, Russell-square, W.C.
Smart, James Joseph, Secretary of the United Service Club, Pall-mall, S.W., and 3, Lambton-terrace, West-bourne-grove, W.
Sundius, Charles C., 54, Picadilly.
Thompson, Frederick, Urmstone Lodge, Wimbledon-park, S.W.
Varnell, Professor George, Royal Veterinary College, Camden-town, N.W.

The following Institution has been taken into Union since the last announcement:—

Clitheroe, Mechanics' Institute.

The articles sent in competition for the Art Workmanship Prizes offered by the Society, were arranged in the room for the inspection of the members.

The Paper read was—

A SHORT REVIEW OF THE SOCIETY'S PAST AND PRESENT ACTION IN THE PROMOTION OF INDUSTRIAL EDUCATION.

By S. T. DAVENPORT, Esq.

The address read by the Chairman of the Council at the opening of the present Session, and the remarks made upon it by the Vice-Chancellor (Sir William Page Wood) and other members, has led me to review the various steps which have been taken since the incorporation of the Society by Royal Charter, in the promotion of Industrial Instruction. I have endeavoured to record the facts as they have occurred to my mind, and I have also appended a few suggestions with reference to what appears to me to remain to be done by the Society, in order to complete the course of action upon which it entered nearly 20 years ago—a course which has gradually become enlarged, and which I believe, if carried out to completion, will add not only to the present popularity of our Society, but so strengthen the body and increase the individual interest of members in its action as to place it in a firmer and more abiding position than it has ever yet attained to, at the same time that it will add to the many claims which it has already advanced, and which have obtained for it so large an amount of approbation and public support.

It appears to my mind that the secret of the Society's success since its incorporation has been the constantly progressive educational course of action which it has pursued. In reviewing the objects for the promotion of which the Society of Arts was established, I find them recorded in the address from the Council on the opening of the 93rd Session, 1846-7, (being the first address after the incorporation of the Society) as follows:—"It was the remark of our Royal President, the Prince Consort, made to a deputation from your Council when waiting upon him on the business of the Society, that the department most likely to prove immediately beneficial to the public would be that which encourages most efficiently the application of the Fine Arts to our Manufactures. The manufactures of this country have, he observed, attained an eminence for solid execution, for perfect finish, for mechanical accuracy, and for cheap production, which distinguish them in these respects beyond those of any other country. But there are some countries that excel ours in the beauty of design, in the perfection of colouring, in symmetry of form, in elegance of pattern; it is the application of the art of design to the mechanical manufactures of this country that is alone requisite to enable her to stand without a rival. Of high art in this country, there is abundance; of mechanical industry and invention an unparalleled profusion; the thing still remaining to be done is to effect the combination of the two—to wed high art with mechanical skill. The union of the artist with the workmen in general—this is a task worthy of the Society of Arts, and directly in the path of its duty." Such were the sentiments expressed by the Prince, our president; such also are the views which have guided your Council in their proceedings during the last year. They have reason to think that this is one of the most promising and valuable spheres of future usefulness to the Society. In accordance with these views, the Council recommended and issued premiums to a large amount for the production of decorative

designs and models. The result of them was, to produce a large series of models of great merit, many of which were rewarded, and some of which have been extensively manufactured and introduced into general use. The Council augur favourably from the success of their first effort in this direction, and expect increased success in the following Session. They therefore propose in this Session very much to extend their list of prizes in the department of decorative arts and manufactures. They much regret that hitherto the artist and the manufacturer have been kept so far asunder; but they rejoice that the Government has already, by establishing Schools of Design, shown its sense of the importance of combining Art and Manufacture. They believe this alienation of natural allies to be most detrimental to both; they believe that it is not vulgar art which ought to be applied to common articles of manufacture, but they believe that the higher the artistic talent called into requisition by the manufacturer the more successful it is likely to become; they believe also that one great means for the promotion of Art and the cultivation of taste, is to surround as much as possible with common objects of beautiful forms, so as to educate the people by the habit of looking on good designs and elegant proportions." To educate the people by the habit of looking at good designs and elegant proportions, was the first object to be attained by the Council, and this they endeavoured to effect by inducing manufacturers to produce articles of every-day use of simple but elegant forms, and, when combined with colour, of a harmonious and artistic character, thereby diffusing a taste and knowledge of Art, and inducing a love for the symmetrical and beautiful by supplying, in cheap materials, of elegant form, objects suited to the familiar uses of every-day life. Having succeeded in inducing the manufacturers to produce artistic designs, the public had next to be taught to appreciate and to purchase them. This object was attained by means of the Exhibitions which were then established, and the first of which, viz., an Exhibition of Select Specimens of British Manufactures and Decorative Art, was opened on the 3rd March, 1847. While pursuing the above course outside the Society, the attention of members within was directed to kindred subjects by means of papers read at its meetings, on Ancient and Modern Art, on the First principles of symmetrical beauty and their application in certain branches of the art of design, on the Harmony of colour, &c.

The success of these efforts grew day by day, and at the close of the session in 1849, we find the Society actively promoting the Great International Exhibition which was held in 1851, an exhibition, the educational value of which cannot be over-stated. But in order that the British manufacturer might not be unduly distanced by foreign competitors, the Society suggested, in the early part of the session 1848-9, that an exhibition of ancient and mediæval art should be held, "to enable the workman of our days narrowly to inspect the productions of his predecessors, executed in times, and under circumstances, which admitted of more careful artistic elaboration than do those in which we are living, and would be highly instructive to manufacturers in their preparation for the Grand Exhibition of 1851."

The Society's efforts to promote an extended knowledge of art and industry, however, did not stop here, nor was it limited to artistic designs and manufactures, for in the same year (1849), in anticipation of the Great Exhibition of 1851, a new series of exhibitions was instituted, the object of which was to place before the engineer, the mechanic, the manufacturer, and the workman, the improved appliances introduced with a view of meeting the requirements of the times, and to give publicity to the productions of "the artisans and mechanics—a class of inventors whose efforts had not at that time had the publicity given them which the Council conceived it is one of the great purposes of the Society of Arts to afford them." Nor did the

Society cease its action, or consider it had fulfilled its mission, when it had attempted to educate the people; induce manufacturers to produce; instructed the workman; and given publicity to the inventions of the artisan and the mechanic. No; new fields for usefulness presented themselves—the Exhibition of 1851 was about to take place—the scientific and artistic skill of our foreign and continental competitors was known—the appreciation of Art by the public, and the desire of manufacturers to produce more perfect specimens of industrial art, was also known; but it was felt that in this country the artist-workman was far behind his foreign competitor, and the Schools of Design were, in effect, little more than a name.

It is not necessary that I should recapitulate all the steps taken by the Society which ultimately led to the Great Exhibition of 1851; suffice it to say that, in the first instance, it found contractors who were willing to provide the necessary funds for the erection of a building, a prize fund, and all other costs and charges incidental to the undertaking; that having obtained for the object a large amount of public support, it became necessary to transfer the management of the Exhibition to a body of noblemen and gentlemen, who were incorporated for that purpose by Royal Charter, bearing date the 15th August, 1850. Of the Exhibition itself, the Commissioners state, in their first report, "of the general admiration excited by the display, it would be superfluous for the Commissioners to give any account; of the beneficial effects which may be anticipated from a spectacle so novel and so wonderful, this is not the place to speak. It will be probably long ere the impulse it has given to industry and civilisation will have reached its highest point, and it is not too much to hope that it will be ages ere that impulse will cease to be felt."

The Exhibition having been closed, we find the Society again at work, anxious to give effect to the lessons taught by the display; and in October, 1851, a letter was received from His Royal Highness Prince Albert, suggesting that in order to the attainment of those advantages to Art and Industry, which it was the object of the Exhibition to endeavour to procure, they would be best effected by a series of lectures on the probable bearing of the Exhibition on the various branches of Science, Art, and Industry. Lectures were accordingly delivered before the Society, the subject selected by Dr. Lyon Playfair for his lecture being the "Chemical Principles involved in the manufactures shown at the Exhibition, as a proof of the necessity of an Industrial Education," in the course of which he states, that, having shown in a former lecture—"On the National Importance of Studying Abstract Science, with a view to the healthy progress of industry—that a rapid transition is taking place in industry, that the raw material, formerly our capital advantage over other nations, is gradually being equalized in price, and made available to all, by the improvements in locomotion; and that industry must in future be supported, not by a competition of local advantages, but by a competition of intellect. All European nations, except England, have recognised this fact. Their thinking men have proclaimed it, their governments have adopted it as a principle of state, and every town has now its schools, in which are taught the scientific principles involved in manufactures, while each metropolis rejoices in an Industrial University, teaching how to use the alphabet of science in reading manufacture aright. Were there any effects observed in the Exhibition from this intellectual training of industrial populations? The official reserve necessarily imposed upon me, as the commissioner appointed to aid the juries, need exist no longer, and from my personal conviction I answer without hesitation in the affirmative. The result of the Exhibition was one that England may well be startled at. Wherever—and that implies in almost every manufacture—Science and Art were involved as an element of progress, we saw, as an inevitable law, that the nation which most cultivated them was in the ascendant. Our manufacturers were justly

astonished at seeing most of the foreign countries rapidly approaching, and sometimes excelling us in manufactures our own by hereditary and traditional right. * * *

"It is well to inquire in what we are so deficient, and what is the reason of this deficiency. Assuredly it does not consist in the absence of public philanthropy, or want of private zeal for education; but chiefly rests in that education being utterly unsuited to the age. * * *

"You may, and I hope will soon, raise an Industrial University, but this should have its pupils ready trained before it adopts them."

Professor Edward Solly, F.R.S., in his lecture on the "Vegetable Substances used in the Arts and Manufacturers, in relation to Commerce," pointed out how the Society of Arts was for a long time the only public body in this country established for the promotion of Industrial Art, but also called attention to the importance of establishing an Industrial Museum, "a place of reference, in which useful knowledge of all sorts would be acceptable to every one, and at all times available for purposes of instruction;" and the Professor concluded his lecture as follows:—"With those who say that we need an enlarged and comprehensive system of national education, I agree heart and soul; but I would even go farther—I say let us have the means of teaching the schoolmaster as well as the scholar; let us, by collecting facts and useful information, obtain those means of instruction in applied science, which are at present almost wholly wanting." Such, in fact, was the universal cry raised by all who studied the Exhibition of 1851. Each lecturer, in his own special department, proclaimed the great want of England, as shown by the Exhibition, to be an increased, national, scientific, and industrial education. The Society of Arts felt the force and truth of the declaration, but it also felt that, before it could step in and aid the scientific education of the industrial classes, it was necessary that the standard of their education should be raised; and we accordingly find that the Council accepted the proposition submitted to it by Mr. Harry Chester, for establishing a Union of the Mechanics and Literary Institutions of the country, a Union which was at once effected, and the successful working and educational advantages of which, to the industrial and working classes, as well as to the Institutions themselves, has been a source of constant congratulation, both in the Council and among the members of the Society. Concurrently with this movement, the Society took steps to establish elementary drawing and modelling schools for artisans and mechanics, and appointed a Committee to carry out the object; and with this view a deputation visited Bradford on the 2nd of February 1862, in accordance with an invitation as set forth in the notice of proceedings issued to the Society at that time, and which was as follows:—

"The Great Exhibition has materially strengthened a growing conviction that one of the most serious disadvantages under which original British manufactures are produced is the want of artistic knowledge and executive ability on the part of the artisans engaged in producing them. Every one competent to judge, admits that the ornamental productions of the French exhibit much more ability on the part of the French workmen in drawing, chasing, &c., than our own. The Council believe that a radical cure for many imperfections of British manufactures, will be found in a much more enlarged and liberal system of art education than at present exists, an education which shall make the power of drawing at least as easy to be acquired as that of writing, and shall begin at an early period of life. The Council are convinced that there is hardly any handicraft in which a workman can be engaged, as a carpenter, mason, smith, &c., which would not be greatly improved by an ability to perceive the form of objects correctly and represent it with precision. At present schools of design are supported partly by a government grant, partly by students'

fees, and partly by voluntary subscriptions. Under this system most of the schools of design are in debt, and the progress of them is rendered doubtful and disheartening."

"The Town Council of Bradford, Yorkshire, a most important manufacturing centre, as yet without a School of Design, have invited a deputation of the Committee to attend a public meeting there, on Monday the 2nd of February, that the inhabitants of the borough, and persons engaged in the staple manufactures of the district of the West Riding may have an opportunity of hearing and considering the views and explanatory statements of the Council."

At the meeting which was held as above, the following resolution was carried unanimously:—"That the meeting fully recognises the great advantages derivable from a self-supporting Institution, calculated to improve the art applied to the manufactures of Bradford and its neighbourhood, and the general taste of all classes, and especially of an elementary drawing and modelling school as an integral part of it, and, in conjunction with the Council of the Society of Arts, will take vigorous measures for giving effect to the same."

A deputation also visited Halifax, where a similar resolution was passed. But the Society did not pursue this portion of its proposed action, as the Government at once proceeded to re-constitute the Schools of Design throughout the country; and I merely refer to the matter for the purpose of showing that the Society of Arts did not overlook, but was prepared to take active measures for promoting and improving, the application of the art of design to industry. About the same period the Society received and circulated the details of a plan proposed by Mr. Thomas Twining, for the technical training of our artisans, in which he referred to the various important and successful establishments in Berlin, Paris, Chalons, Angers, Aix, &c., observing "that the plan he had adopted in arranging his remarks is that which seemed most likely to render them convenient to those who might be desirous of giving a full consideration to the subject of a National College of Trade."

The Society subsequently co-operated with the Royal Commissioners of the Exhibition of 1851, in forming a Trade Museum of Animal Products, which collection is now deposited in the Museum at South Kensington.

I have stated that the Council selected from among the many propositions suggested, and pressed upon its consideration, that by Mr. Harry Chester—as affording the broadest basis for effecting the universally desired amelioration of the educational condition of the artisan and working classes. The soundness of judgment which dictated that selection, has since been abundantly evidenced, but, in order to give point and value to the educational classes in Institutions, it was necessary not only to induce the establishment of classes, but also to give a motive to continuous study in them. This the Society effected, and is still effecting, by the systems of Examinations it instituted—the prizes it offered—the Government nominations it obtained for pupils who received certificates, and their efforts were greatly strengthened by the prize which the Prince Consort offered, and which has since been continued by Her Majesty, and awarded to the student who obtains the largest number of first-class certificates and prizes during four consecutive years. This work of education and examination it has been and still is pursuing. During the ten years of its progress it has published many papers on education, and an important report on the question of Industrial Instruction. In that report, which was first published in April, 1853, and again re-issued in May, 1867, it is stated that the Council resolved "to appoint a Committee to take into consideration, and report, how far, and in what manner, the Society of Arts may aid in the promotion of such an education of the people as shall lead to a more general and systematic cultivation of Arts, Manufactures, and Commerce—the chartered objects of the Society;" and the Committee in

report stated "that it would be absurd, for example, to suppose that any school could turn out a ready-formed machine maker; yet the labour of the mechanical painter, in giving practical instruction to his apprentice, will be not only lightened but made more efficient, if the latter had been previously taught mechanical drawing—had learned the properties of the lever, the pulley, the wedge, and knew the nature of and difference between cast-iron, wrought-iron, and steel; while, therefore, the practical training would be left as heretofore, cannot be denied that a knowledge of the principles of the sciences on which arts or trades are founded is an indispensable element in the instruction of the well-skilled workman. * * * Innumerable rewards exist at present for the cultivation of classical learning—why should there be none for the promotion of industrial knowledge?" Notwithstanding all the efforts made, a system of technical instruction still remains to be carried out, but the Council nevertheless considered that such had been the industrial and art progress made in this country & they were justified in proposing and succeeded in obtaining the support of the country for a second International Exhibition, viz., that of 1862. The Exhibition of 1862 was a display of Art and Industry of which England may well be proud. It resulted in placing the ingenuity and mechanical skill in a far higher position than it had ever previously attained to; its intellectual powers had also increased, but the want of technical and scientific instruction was and is still felt as a deficiency which must be met if British manufacturers are to hold a successful rivalry with their continental competitors in industries. The Society of Arts accordingly again stepped forward to assist the workman, and by availing itself of the aids of science and daily improving arts of chromo-lithography and photography, and also of metal casting, has been enabled to institute a new series of competitions for the Artist-Workman, at which time it has awarded prizes for the best production in metal work, ivory carvings, China paintings, wood carving, &c., &c., thus recognising the skill of the workman and placing him in the foremost rank of executors, and doing for him that which the International Exhibitions have done for the capitalist and employer, and what examinations have done for the student in reference to primary education. The progress now sufficiently indicated, not only what has been done, but is doing, and it remains for me to make in my concluding remarks what it has not done & what it may possibly carry on to completion the great work in which it has been engaged, and to which it has been pointing for so many years past, I mean technical education, in connection with the Society of Arts and its various bodies, of lectures and classes, conducted by the Society, by means of which instruction in Art and Science, and its bearings upon industry, may be given to our workmen, as well as to those who may hereafter

At the present moment it is, jointly with the Company of Coach and Coach Harness-makers, affording its patronage to the workmen engaged in that trade who are about to hold an exhibition of the products of their skill and industry. Out of London it has contributed to a prize fund for the promotion of improved design and increased skill and ingenuity on the part of the Whitby jet-workers; and the question at once arises, would it be possible to induce a combined action on the part of the 80 City companies, the Chambers of Commerce, and other bodies in aid of the industrial education of the youths of the present day, as well as to encourage the skilled workman by the offer and award of prizes in each of their respective industries.

The Society of Arts has already begun the work, both by awarding prizes to skilled workmen and the institution of lectures on the application of science to industry; it will doubtless continue and extend its action in both directions; but to attain real instruction in science, more than lectures are necessary. Classes under competent Professors must be formed, if industries are to be benefited. At the close of the Great Exhibition of 1851, in order to attain more education in technical knowledge, it was said that the effort should be made to educate downwards—to give less classical and more practical education. The Society did not accept that proposition, but, beginning with the working classes, has been endeavouring to educate them upward; and now that its examinations have enabled their education to be tested and the fitness of youths to be advanced into classes where they may acquire precise knowledge as affecting industries, one of the difficulties in the way of the establishment of classes for industrial instruction is got rid of. The certificates of our own examiners, of those awarded at the Oxford Middle Class Examinations, which arose out of our own action, of the London University and others, should be the passport to our industrial classes.

If, then, the City Companies could be induced to co-operate with the Society of Arts in establishing a system of instruction and a test of the degree of knowledge acquired by those who are apprenticed by their corporations; if they would assist and co-operate with the Society of Arts, by offering and awarding prizes to the skilled workman, the Society might again create for the benefit of the public, Annual Displays and Exhibitions of the Products of British Industry, to which British manufacturers might send selections from their yearly commercial products, not advertising specimens got up for great exhibitions regardless of cost; the patented and mechanical inventions of each year might also be added, as well as samples of raw produce and imports, or selections from them. To effect the latter object it might be necessary to urge upon government the propriety of its doing for commerce what it already does for literature, by compelling the deposit in our national library of a copy of each work produced for sale; in like manner it might compel the deposit, when required, of samples of new imports.

Thus we should have an aggregation of the products

I have no doubt that the members of the Society and the public would respond to an appeal for funds if a comprehensive scheme supported by the co-operation of the City Companies and others, were placed before it. I also believe that the Society, which has an equitable claim to a portion of the surplus profits arising out of the Great Exhibition of 1861, a claim which it has never yet pressed upon the Government and the Royal Commissioners, might fairly advance such claim now the country has become possessed of a large portion of the estate purchased with that surplus and handed over to the government, as has been publicly stated at a price far below its market value.

Let the Society of Arts proceed then in its onward course, let it act the part of broker or middleman with energy; it knows what is the demand on the part of the public; it also knows how to obtain a supply to meet the demand. To hesitate or delay action, is to fail in its duty; to supply the demand is to add new honours to those it has so deservedly won during the century and upwards of its existence.

PRIZES TO ART-WORKMEN.—It would ill become me, as an officer of this Society, to criticise or express any opinion upon the various articles which have this year been received in competition for the Prizes offered to Art-Workmen; that is one of the duties which will be discharged by a Committee appointed by the Council; nor is it necessary that I should enter into any lengthened statement relative to the course which the Society has adopted relative to the offer of those prizes. Invited in the first instance, to co-operate with the Company of Painters Stainers for the offer and award of Prizes in promotion of their special industry, it was natural that other bodies, seeing the success which attended the efforts of that Company, should desire to apply a like stimulus to their own trades.

Accordingly, we find the Society of Wood Carvers applying to the Society of Arts to co-operate with that body in the offer and award of Prizes for the promotion of their special Art industry, and the Exhibition of Wood Carving, held in June, 1863, was the result.

The Council of the Society of Arts, seeing that there was a growing desire on the part of the Art-workmen to come forward and compete for honours in their several handicrafts, appointed a Committee, in March, 1863, "to consider and report what prizes the Society should offer for the encouragement of Art-workmanship applicable to manufactures," and, upon the recommendation of that Committee, the Council decided to offer prizes for the successful rendering of designs in the undermentioned processes of manufacture, according to the directions detailed in each case.

1. Modelling in terra cotta, plaster, and wax.
2. Repoussé work in any metal.
3. Hammered work in iron, brass, or copper.
4. Carving in ivory.
5. Chasing in metal.
6. Enamel painting on metal, copper, and gold.
7. Painting on porcelain.
8. Inlays in wood (marquetry or buhl), ivory, or metal.
9. Engraving on glass.
10. Embroidery.

The designs will be by artists of great reputation, to be translated into the various modes of workmanship; and photographs and castings of such designs will be sold by the Society, at the Society's House, at cost price, to persons desiring to be competitors."

In accordance with the above recommendation, a list of prizes was prepared and issued in May, 1863, and in October of the same year 72 works were received in competition. The works received were exhibited in the Society's room; and a list of the prizes awarded will be found in the *Journal* (See Vol. 12, page 75).

The success of this the Society's first effort, in connection with general Art industry, was so far satisfactory as to induce the Council to prepare a second list of

subjects, the response to which will this evening be seen and judged of by the members.

I cannot conclude these remarks without congratulating the Society upon the continuous and steady growth of a desire on the part of the industrial classes to come forward and exhibit specimens of their skill and industry—a desire which has been abundantly evidenced by the Exhibitions held in South Lambeth last year, and more recently in the North of London. Other exhibitions of a like character are announced as about to be held in Marylebone, in Lambeth, and also by the workmen employed in the coach-making trade.

In connection with the latter Exhibition the Society of Arts has offered some special prizes, which will be competed for in February next. A list of these prizes is given below. The Exhibition will take place in the hall of the Company of Coach and Harness-makers.

OPERATIVE COACHMAKERS' INDUSTRIAL EXHIBITION.— SPECIAL PRIZES.

The Committee have great pleasure in submitting the following as a list of the Special Prizes promised up to the present time:—

The Society of Arts offers a prize of £10 together with the Society's Silver Medal, for the Best Set of Working Drawings for a Private Carriage, showing the construction of its various parts. Scale 1 inch to the foot.

Also £5 for the Best Specimens of Heraldic or Ornamental Chasing in Silver, Brass, or Copper, suitable for Carriage or Harness.

Also £5 for the Best Specimens of Heraldic or other Metal Ornaments produced by Electro deposit, suitable for Carriage or Harness Ornamentation.

The Worshipful Company of Coach and Coach Harness Makers place three Bronze Medals at the disposal of the Judges.

Also the Master of the Company (Thomas How, Esq.) offers £5 for the Best Design of an Open and Close Carriage combined. Scale 1 inch to the foot.

Mr. G. N. Hooper offers Three Guineas for the Best Drawing of a Town Barouche, on under and C Springs. Scale 1 inch to the foot. Open to foremen, carriage operatives, and apprentices.

Also Two Guineas for the Best Drawing or Model of a Light Hospital Carriage, to convey the sick poor. Open to all comers.

Mr. G. A. Thrupp offers Two Guineas for the Best Stuffed and Quilted Carriage Cushion in blue Morocco leather. Open to coach trimmers only.

Also Two Guineas for the Best Drawing in Pencil, upon Paper (half the full size) of an Under Fore-carriage for Elliptic Springs, of usual or original design. Open to apprentices and improvers.

Mr. J. F. Woodall offers Two Guineas for the Best Specimen Panel of Carriage Painting, eight Plain or Ornamental.

Also Two Guineas for the Best Finished Pad and Bridle, for Pair-horse Harness. Open only to harness makers working in carriage factories.

Also One Guinea for the Best Covered Carriage Dash-Iron sewed by hand.

Mr. Barlow offers Three Guineas for the Best Working Drawing (full size) of Ornamental State Lamp, of New Design, suitable for a Coach or Chariot.

Also Two Guineas for the Best Full-size Model of Brougham or Barouche Lamp, of New Design, uniting perfect ventilation and reflecting powers, to burn candle, oil, or other material.

Also Two Guineas for the Best Complete Set of Full-size Working Models of Furniture for Pair-horse Harness, of New Design. (Chased work not to be introduced.)

Or One Guinea for the Best Complete Set of Full-size Working Drawings of Furniture for Pair-horse Harness, of New Design. (Chased work not to be introduced.)

Also Half a Guinea for the Best Six Full-sized Models

or Twelve Full-size Working Drawings of Bridle Fronts, of New Design. (Chased work dot to be introduced.)

Also Half a Guinea for the Best Six Full-sized Working Drawings of Bridle Rosettes, of New Design, Chased or otherwise, from $2\frac{1}{2}$ to $2\frac{3}{4}$ inch diameter.

Also One Guinea for the Best Six Full-size Models or Twelve Full-size Working Drawings of Carriage Door Handles, of New Design. (No chased work to be introduced.)

Also Half a Guinea for the Best Specimen of Hard Solder Plating (silver or brass).

Also Half a Guinea for the Best Specimen of Soft Solder Plating (silver or brass).

The Committee offers—

For the Best Set of Working Drawings of Improved Street Cabs.

For the Best Specimen of Heraldic Painting.

For the Best Specimen of Decorative Coach-carving.

For the Best Set of Working Drawings for an improved Under Fore-Carriage for a Brougham, combining lightness and strength.

For the Best Specimen of Ornamental Carriage Painting, Imitation Pedestal Painting, Sham Caning; also for harmonious combination of Colours and perfection of surface.

For Parts of Harness, Improved, of Full-size or in Model-size, or the Best Design of improved Harness.

For the Best Covered Carriage Dasher, or Wing, or Seat Border, sewed by hand or machine.

For the Best Method of Detaching Fallen Horses quickly, either in front or rear.

For the Best Cushion, Stuffed and Quilted in any Material.

For the Best Design for New Mode of Trimming a Carriage Door.

For the Best Design for a Hammercloth, combining good effect and economy in cost.

DISCUSSION.

THE CHAIRMAN said it was now his duty to invite discussion on the paper they had just heard read. The attendance this evening, and the manner in which the paper had been received, convinced him that the members appreciated, as he did, the great zeal and ability with which Mr. Davenport discharged his duties as an officer of the Society. He could not refrain from paying this tribute to him on an occasion when no doubt a great many of his personal friends were present. On previous occasions he had expressed himself with regard to the good fortune of this Society in being represented by three officers, all of whom possessed considerable talent, and who not only exercised their talent for the advancement of the best interests of the Society and the objects for which it was established, but who also contributed, by unity of purpose and action, in a most remarkable degree to the advancement of all those great objects for which the Society was established. He hoped the discussion would show that the members appreciated those services, and that the action of the Council for the last ten or fifteen years, in endeavouring to reform the education of the middle classes and of the Art-workman, was in harmony with the requirements of the times, and would meet with the hearty support and co-operation of the members at large.

Mr. H. COLLE, C.B., remarked that there was one paragraph in Mr. Davenport's paper with which he could not agree. That was with regard to the Government compelling the deposit in some national museum of a copy of each manufactured work produced for sale. He thought Mr. Davenport was mistaken in supposing that Government could compel people to make such a deposit. For his own part he should be sorry to see any such compulsory law as that hinted at. Indeed, he thought it was not creditable in the present day that there should be a law compelling authors to deposit gratuitously copies of their works in the library of the British Museum and

other public institutions. It was not an agreeable thing for a public officer, in the exercise of his duties, to be constantly summoning publishers to the police-court for not conforming to the law in this respect. He believed it was detrimental to literature, and he conceived it would be so to manufactures; and further, he felt certain that to build a huge Babel to hold specimens of the character named—good, bad, and indifferent, as the case might be—would be the most tiresome and uninteresting to visitors. He would now turn to the Exhibition arranged for inspection to night, and he must congratulate the competitors upon it. Although he had been unable to do more than take a cursory view of the objects, he felt assured that a considerable advance had been made in the quality of the work over that of last year. He had no doubt this idea of inducing artist-workmen to exhibit specimens of their handicraft would fructify. It would go on increasing, as was the case with the Royal Academy, which more than a century ago had started from small beginnings. In the outset of such a work as this, however, no doubt there would be some errors in detail which might require amendment, more especially as to the conditions attaching to some of the prizes offered. He feared that these conditions in some instances had perhaps prevented the sending in of so many specimens as might have been expected. For instance, a dozen casts of the bust of Clytie had been sold to workmen, but one only had been finished and sent in. This led him to fear that there was some condition connected with that matter which impeded competition. It might be that the bronze was not delivered in time for the work to be done in the workman's overtime, for it should be remembered that these things were executed in the workmen's overtime. He hoped the same bust would be competed for next year, so that the labour of those who had bought the cast this year might not be thrown away. Then again it might be considered that the works which the Council had put forth to be done were not such as when finished would be saleable commercial articles. That was no doubt partially true, though in their selection the Council had endeavoured to bear that principle in mind. He thought, however, he saw among the articles exhibited some which might properly be bought for the South Kensington Museum, and he hoped the Lord President would take that view. As an individual member of the Society, it occurred to him whether, in the selection of objects to be presented for execution in their next programme, it would not be well to take the workmen themselves into consultation, and ascertain which they would suggest as most fitted for the purpose; and he also thought the object might be still further promoted by a little co-operation on the part of those who were interested in special manufactures. He thought the Council would do well to receive suggestions from those quarters as to the subjects to be selected for competition. He would only further remark, that though some of these articles now exhibited might not be immediately saleable, yet he believed in many instances they would be the means of producing commissions for the producers of such articles. He might state that at South Kensington wood carvings were wanted, and he saw specimens this evening which led him to think that the persons who executed them might be called on to do something for that national establishment. He was gratified at seeing indications of a new branch of industry springing up, viz., glass mosaics. The heads exhibited this evening were the first publicly exhibited specimens of glass mosaics by English artisans he had ever seen. He considered these worthy of great attention, as he was satisfied before many years there would be a very extensive application of glass mosaics for decorative purposes. He had reason to believe that more than one of these specimens had been produced by females. It was a branch of industry in which that sex might be well employed, and he would only throw out the hint to those who might hereafter de-

sire to engage in it, that, as an indispensable preliminary, they should possess a sound knowledge and power of drawing.

Mr. D. ROBERTSON BLAINE had listened with great pleasure to the admirable paper; and his single objection to what had been advanced in it was confined to that part which had been alluded to by Mr. Cole, the compulsory deposit of specimens of manufactures at the expense of the manufacturers themselves.

The CHAIRMAN, quoting the passage of the paper referred to, said the suggestion only applied to "new imports" of raw materials employed in manufactures.

Mr. BLAINE said the suggestion was an admirable one, if it were done at the expense of the Government; otherwise he took exception to it. In the case of the precedent that had been quoted, viz., on the compulsory deposit of copies of literary works in public libraries, he knew it operated in many cases as a great hardship upon authors and publishers, especially in the case of the more expensive works. If they wanted copies of works to be deposited, he thought the Government and the universities ought to pay for them. With regard to the many beautiful works which they saw before them, they afforded illustrations of the rapid advance which was making in Art-workmanship in this country. He referred with great satisfaction to the testimony borne by the French artisans who visited the Great Exhibition to the great progress made in this branch of industry by the workmen of this country. That was one great proof of the benefits of international exhibitions. The French people were now pressing upon their government the importance of following the example of this country in promoting schools of art, because they saw the wonderful progress which had been made in England since the Government Schools of Art had been established.

Mr. PETER GRAHAM, referring to the selection of the special objects for execution, remarked that he regarded this as a necessary step, in the first instance, as serving for a guide to the competitors as to the class of works on which their skill should be exercised. On future occasions he thought more scope might be allowed, and that workmen might be permitted to bring their original works as proofs of talent in design, as well as power of execution. It was due to Mr. Davenport to thank him for several excellent suggestions he had thrown out in his paper. It would be a most desirable thing to obtain the co-operation of the wealthy City companies and guilds; take, for instance, the Goldsmiths' Company, he thought it was rather a reproach to that important company that it had not come forward to encourage by prizes the development of those beautiful arts with which it was identified. It possessed immense wealth, and he did not know how it could promote the interests of the guild, or do anything more creditable than to offer prizes in every branch of the goldsmith's art. The same remarks applied to other companies. One of the poorest and most obscure of those guilds, the Painters Stainers, had been the first to set an example in this direction. He had not yet minutely examined the collection of objects before them, but he could see at a glance that there was a great advance upon the display of last year; and no doubt if it was carried on in a right spirit they would see improvement year by year, till the art workmen of England were equal in execution to those of any other country in the world.

Mr. WINKWORTH said that he thought his friends Mr. Cole and Mr. Blaine had occupied too much time in discussing a point which was not important to the immediate object of the paper, and respecting which they had not quite apprehended Mr. Davenport's precise meaning. He had not, as they supposed, approved the policy, amounting to confiscation, of compelling authors to deposit copies of their works at the British Museum, the Universities, and other public institutions; but, assuming that it was to continue a law of the land, might it not be usefully extended, in the way suggested in his paper, to the pro-

motion of Art-Manufacture education? He (Mr. Winkworth) also doubted whether, as the articles in and around the room which had attracted so much attention—and to some extent admiration also—were sent in competition for prizes, it was judicious or fair to anticipate the awards of the adjudicators hereafter to be appointed, by specially noticing certain specimens of art in the room which, in the opinion of the speaker, Mr. Blaine, were beautifully designed and executed. He would now recall the attention of the Society to the paper which had so much interested them, and justly so. Mr. Davenport had favoured them with a well-digested historical epitome of the action of the Society in the direction of industrial education, and in so doing could not fail to pay a tribute of recognition to the services Mr. Harry Chester had rendered to the cause of adult education in all its branches, by suggesting and initiating a system of competition which had borne most gratifying fruit, and the benefits of which were being daily extended. That which he had organised might be introduced into a sphere of education which should give to the artisan a kind of technical knowledge, of which English workmen were for the most part ignorant or were only partially acquainted. He had in his paper suggested several new directions, as, for instance, lectures and classes, conducted by professors, by which instruction in art and science, so far as they bore on skilled industry, might be properly communicated; and one original way in which this might be encouraged, the action of the trade guilds and companies, might be invoked, as in the case of the Painters Stainers' Company and others. To this he (Mr. Winkworth) cordially assented, but Mr. Davenport should not indulge the hope that the suggestion would meet with universal acquiescence, for it must not be forgotten that many of these corporations had outlived the trades for the promotion of which they were ostensibly established. Who, for instance, could tell them what was the particular craft originally contemplated by the Loriners' Company? Others, again, as the Fishmongers' and Spectacle-makers, did not seem to afford scope for the offer of prizes for new discoveries or appliances in their particular branches of trade. The bulk of the members of many of the City companies had in fact no idea of the crafts they were apprenticed to learn, and the secrets of which they were sworn not to divulge. Others again had no funds that could be legally diverted to objects external to their own. But, on the other hand, the City companies were in the aggregate wealthy and patriotic, and whether their own specialities afforded scope or not for the offer of prizes to elicit talent in the cultivation of them, they would no doubt, if suitably approached, be found willing to contribute of their abundance towards objects so legitimate and praiseworthy as Mr. Davenport in his paper had so luminously pointed out. He had only in conclusion to repeat that he felt much indebted to Mr. Davenport for his well-arranged and well-digested paper on topics at this moment so generally interesting, and he confidently anticipated that the result of the discussion would be to affirm the propositions he had submitted, and to suggest means for carrying them out.

Mr. GEORGE GODWIN, F.R.S., could not allow the last observation to pass without comment, as he confessed he did not take the same satisfactory view of the objects exhibited which the hon. gentleman who preceded him had done. That it was much better than the collection on the previous occasion there could be no question, but that it came up to the inducements held out by the Council of the Society he was unable to say. Premiums to the extent of nearly £600 were offered by the Society for objects in all these branches of art industry, and though there were many excellent works in the collection, he was afraid when the majority came to be critically examined, a small portion only would be found entitled to high commendation. The inference to be drawn was that there was something more to be done than the mere offering of prizes. They had to labour to induce a greater appreciation of the necessity of education. Looking at the means

now afforded to working men and to those above them, it seemed to him discreditable that the response to the invitation had not been greater. During the last few months he had been frequently called upon by old workmen, journeymen carpenters, bricklayers, and plasterers, for advice as to what they could do for their sons, in order to get them out of the fixed drudgery in which they themselves had been compelled to labour for so many years. His simple advice was, and he wished the hint might find its way into the workshops of this country, let them learn drawing. There were schools of design throughout the metropolis, and in nearly every large town. If it was necessary, the parents must make a little sacrifice to enable their children to do this. In so doing they would make their children to rise above their own position. Their course was easy; schools of design were plentiful; competitions were open; there were the examinations and prizes of the Society of Arts; and there was a wide field open for the development of the fine arts for decorative purposes, domestic and ecclesiastical. The moment a man showed ability he was sure to be taken by the hand, and to raise himself a step beyond the position in which his father was toiling. They wanted in addition, however, some little effort on the part of manufacturers and from the large builders. He thought the system of apprenticeship had been too much neglected. It should be urged upon the large builders and others that they should aid their men in pushing forward their sons; that they should take the sons into their establishments, and enable them to gain a superior position in their trade. It was a lamentable fact, that notwithstanding what had been already done, the great body of artisans of the present day were universally inferior to the artisans of 70 years ago. They could not get the same number of good bricklayers, or an equal number of carpenters with the same amount of geometrical knowledge as formerly. The system of contract work had led to a demand for quantity rather than quality. The absorption of various trades into one person's hands, in the shape of contractors, had destroyed emulation, and stood in the way of the small masters. As an instance he referred to the fine plastering which was to be seen in some of the older houses in London. There were not men now to be found to do this work. It therefore behoved this Society to go on in its course of stimulating the education of the artisan. At the late Exhibition of the Architectural Museum, only five specimens were sent in for competition for prizes, varying from £5, £10, to £20, and none of these possessed sufficient merit to induce the Council to award the prizes offered. That showed how small the response had been there; and it was small on the present occasion, taking into consideration the large sum offered in premiums by the Society of Arts. The notion had been entertained by himself and others that it would be well to invite the skilled artisans of London to a conference in this room, in order that they might state why they had not competed more largely, and under what circumstances they would compete? Such a proceeding would put them in possession of facts which would enable them to obtain larger results. What was sought for by these competitions was the encouragement of a more intimate union between the fine arts and the useful—the wedding of Venus and Vulcan. Speaking of the latter, he was sorry to note how small was the response as regarded hammered iron and brass work. It was ridiculous that there should be only two or three small specimens of this description of work sent in in response to the appeal that had been made. He was sure all present would thank Mr. Davenport for his paper. He was not certain that they could look to the great City companies for more than pecuniary aid; but the competitors would require to be assured from the beginning that those who were to be the judges of their work had some practical acquaintance with it. Companies were not qualified themselves to be the adjudicators of the prizes, because the workmen would not have confidence in their

judgment. With regard to lectures, they were important and no doubt valuable, but they would not alone make good artisans or good workmen. There must be actual practice in the studio and the workshop.

Mr. B. WATERHOUSE HAWKINS would venture to support the suggestion made by Mr. Cole and repeated by Mr. Graham, viz., giving a little more liberty in the conditions of the competition, to the extent that while certain photographs and models might be selected as the type of the work to be performed, the workmen should be at liberty to enlarge upon the original design, that it might be employed in the decoration of some article of utility, so that the person who succeeded in that direction might find his reward in having produced an article, which in itself would be saleable, and not a mere abstract work of art. In the production of these works, it must be remembered that the artisan occupied his time after the ordinary hours of labour, and hence he thought the time allowed was scarcely sufficient. The greater part of the work could only be performed during the evenings in summer time. He was inclined to think that by giving a longer time they would have a larger collection of works sent in.

Mr. THOMAS JONES, with reference to the co-operation of the City companies, remarked that so far from the Goldsmiths' Company assisting in the production of works of art, their practice in testing the purity of the metal employed, and sent to them for that purpose, did much injury to them. Works of excellent truthfulness and perfection of form sent there to receive the certificate of the company that the material was of a given standard, were, from the manner in which they were treated, unnecessarily disfigured, and rendered unfit for sale until they had a second time passed through the hands of the workman. It would be a great benefit if this Society could become the means of inducing that distinguished company to treat the works of art confided to them a little more carefully. It had been stated that the Painters Stainers' Company had been the first in the movement of promoting competition of the character under discussion this evening. He, however, believed it was the Loriners' Company to which that honour belonged. Unfortunately, however, the effort was discontinued, in consequence of a feeling on the part of some of the members of that guild that the funds ought not to be diverted to the rewarding of persons outside their own pale.

Mr. P. L. SIMMONDS cordially approved of the suggestion of Mr. Davenport, that raw materials of commerce should be deposited with the Society, for the purposes of scientific examination and report. There was at present no convenient public place of deposit where such articles could be seen and examined. He knew many new oil-seeds, fibres, gums, paper materials, &c., were received by brokers and merchants in this great commercial port from time to time, which were either entirely overlooked or but little appreciated, and yet many of these might become most important for manufacturing use. Mr. T. C. Archer had a few years ago read a paper before the Society "On some New Articles which had come into Commerce in the Port of Liverpool," but they scarcely ever heard of the new articles which were received in London. The Society had already been the means of introducing to public notice many valuable articles of commerce, such as gutta-percha and Balata gums, Indian silks, new oils, &c., and could do much more good if specimens were deposited for examination by importers and others.

Mr. PHILIP PALMER said the object of the co-operation of the City companies had been introduced by him at the first meeting of the session. He would follow up what he then said by adding, that in the observations he submitted, he did not mean that companies should institute separate competitions or separate exhibitions, but that they should render their assistance to the competitions of this Society. In this respect he apprehended there would be no great difficulty in obtaining the co-operation of such

companies; for instance, the Mercers' Company might contribute prizes in connection with textile fabrics. The Grocers' Company might render their assistance in the matter of colonial productions, as suggested by the observations of the last speaker. The spectacle-makers' operations might, he apprehended, be extended to the whole range of optical instruments. He agreed with Mr. Godwin that it would be a great advantage to all branches of trade that a proper apprenticeship-system should be established.

Mr. JOSEPH ASH stated his belief that the small exhibition in wood carvings at the Architectural Museum, alluded to by Mr. Godwin, arose from the almost entire absence of practical working men in the Council of that Institution, who acted as the adjudicators of the prizes. He thought it of the utmost importance that the competitors in such competitions as these should have confidence that the merits of their works would be decided by a competent tribunal of practical men.

Mr. GEORGE LOCK claimed to be the originator of the scheme for prizes in wood-carving which had called forth the present competition in that department; and he begged permission to say a few words on points which had been suggested by this and the preceding display. He agreed with the last speaker, that the paucity of specimens at the Exhibition of the Architectural Museum was in a great measure due to the cause which had just been pointed out; and he suggested that in these exhibitions it should be a condition, that the jurors appointed to decide on the merits of the competitors should include a fair proportion of practical men in each branch of the subjects. He felt if that was not done these competitions would suffer. With respect to the subjects selected by the Council for the wood carvings, he believed there was no cause for complaint, inasmuch as in addition to the models and photographs issued, there was in the programme this year a series of prizes offered for original works in wood carving, no design or model being prescribed. Complaint had been made on the part of a few employers, who were not themselves Art workmen, with regard to the indefinite period for which the articles were required to be left in charge of the Society. Some tradesmen considered it an inconvenience to lose a portion of their stock for a lengthened period, and he thought it a matter worthy of consideration previous to the next competition. From some quarters he had heard complaints of want of proper information from the officers of the Society. He did not mention this as implying any neglect on the part of the officers, for he was quite aware of the vast amount of extra labour which these exhibitions entailed upon them. Another point he would suggest was a more extended publicity being given of these competitions; and with that view he suggested that they should be advertised in those newspapers which were mostly read by working men. The mere announcement in the Society's *Journal* was not sufficient, as that publication was not seen by working men. He had been told by one of the promoters of the North London Exhibition that not one of the fifty persons who acted with him had heard of this intended competition. He concurred in the suggestion that the competitors should to a certain extent be consulted as to the subjects which should be selected as models on which they should exercise their skill. Mr. Lock then alluded to the proceedings of the Society in respect of its competition of a similar character to this in the latter part of the preceding century, when the sculptors Banks, Nollekins, and Bacon were among those receiving rewards. The last-mentioned artist succeeded in carrying off several valuable prizes, and the advantage of the system to him in after-life was acknowledged in a letter to the then Council of the Society. In conclusion, Mr. Lock expressed a hope that the Council would consider the desirability of exhibiting ancient works of art in connection with this display of the articles sent in competition for prizes. He believed that such a course would give additional interest, and would be of great value to the competitors and Art-workmen generally.

Mr. H. HALE said one reason why the response on the part of the wood-carvers had not been more extensive was to be found in the fact that that class of workmen had been so much occupied by the pressure of business of their employers during the last year, that they had no leisure to prepare objects for this exhibition.

The CHAIRMAN said, the time having arrived for closing the discussion, he thought Mr. Davenport might congratulate himself on his paper having elicited one of the best and most useful discussions of the session. There were, however, one or two observations, especially those of Mr. Lock, which required some notice from him as Chairman of the Council. Mr. Lock had stated that complaints had been made in some quarters of the length of time the specimens were kept in the Society's charge, and that whilst such specimens were kept out of stock they might become unsaleable. Now, with regard to articles taken out of a tradesman's stock, if that were known to be the case they would not be admitted to competition, for it was not the object of the Society in these competitions that persons should compete who were able to keep works in stock, and employ others to do the work. The great object was to do for the Art workmen in his special handicraft that which had already been done in another direction in testing the knowledge of candidates by the examinations instituted by the Society. The Society sought to stimulate the Art workman by giving opportunities for testing his skill, and by placing before him models and photographs of the best examples in each branch of industrial art. With respect to the character of the subjects and the conditions of the competition, he might state that out of the 97 articles sent in, 34 were in connection with that division of the programme in which no restriction was laid down as to choice of subject, and for which no examples were prescribed. The competitors were free to do that which they thought best suited to their individual talents and powers. He could not help alluding to the beautiful carving of the head of a child behind him, in illustration of this statement. No model or photograph was furnished for that beautiful work. Having referred to some other works exhibited, the Chairman went on to remark upon the co-operation of the City companies in this work. He said it was a difficult but an interesting question. Taking the twelve leading companies in their order of seniority—the Mercers, Drapers, and Grocers—might be asked to offer prizes for the finest productions of the loom in all the branches of textile fabrics. Again, the Fishmongers' Company might be brought into the field. The most beautiful of old china was replete with forms of animals in all sorts of relief. That company might offer prizes for the best designs in earthenware or china exhibiting the best drawings of the denizens of the seas and rivers of this country. Of the Goldsmiths' Company he need say no more, now that it was to be hoped that instead of converting watch cases into cocked hats they would test the quality of the gold and allow the beautiful work of the lathe or the tool to be returned to the owner, uninjured, and offer prizes for the best specimens of chasing or of ornamental jewellery. The Vintners' Company again might, in like manner, do their share in this good work, and encourage the artistic embellishment of metal work, by offering prizes for ornamental designs, in which the beautiful stem, leaves, and tendrils of the vine might be most elegantly introduced, and with which many of the most beautiful ancient bronzes were ornamented. In this way something might be done by the great majority of the City companies, but it could only be effected by great attention and labour on the part of the Council, and whether they would have time to enter upon it during this year he could not at present say. It was a pleasant thing to the Council to hear a certain amount of fault found with these proceedings, and to have attention directed to any weak points in the system by so friendly yet so powerful a critic as Mr. Lock. He believed, however, they were in the main fulfilling the

wishes of the members in the course they had pursued with respect to these Art workman prizes; and when it was said that intending competitors could not gain the necessary information from the officers to enable them to send in their works in time, he was sorry that such a statement had been made, as he was convinced some misunderstanding must have occurred, for no workman could have applied to Mr. Foster or Mr. Davenport without obtaining the fullest information it was in the power of those gentlemen to give. Another observation required remark, viz., that relating to want of sufficient publicity being given to the rewards offered by the Society. He believed Mr. Lock did not know what had been done by the Council, who had distributed bills containing their programme very freely among the principal workshops; and to prove that the workmen were aware of the competition, he would state that nearly 600 copies of the photographs and engravings had been bought by the workmen at the Society's house; and further, with respect to the insufficiency of the time allowed, he would add that the notices were issued in February for works to be delivered here in the November following. Then, with respect to the time the articles were delivered, and the period which elapsed between the exhibition and the adjudication of the prizes last year, he must say that the works were not sent in till June, and they could not name a day for the distribution of the prizes until the Prince of Wales became the President, and appointed a day for that purpose; and he believed the recipients of the awards were more gratified at the honour of receiving them from the hands of his Royal Highness, than disappointed on account of the time they had to wait for them. On the point referred to by Mr. Godwin, who spoke from his own knowledge, which was very extensive, that the workmen of the present day were not equal in skill to those of seventy or eighty years ago, he thought that remark required some qualification. They might not be able to get plasterers to do the splendid work which they saw in some of the old city halls. It was a description of work not executed now, because the most beautiful forms of ornamentation were produced more quickly, and they could not afford the time for it. But if they tested the skill of the workmen as a whole—in the precious metals, in plate, in china painting, or the works of the loom, they knew that the French artists had expressed their surprise at the wonderful progress made in this country.

Mr. Godwin said the remark he had made applied merely to building operations.

The CHAIRMAN said that he would carry his remarks no further, but he would ask the meeting to thank Mr. Davenport for his very interesting paper, and to congratulate him on the interesting discussion which had followed the reading of that paper.

The vote of thanks having been passed,

Mr. DAVENPORT in acknowledging the vote of thanks said in reply to the observations made by Mr. Cole and Mr. Blaine, that the idea which he intended to express was this—if Art, Manufactures, and Literature, are beneficially promoted by the protection which the government of the country gives to the author, the artist, the designer, the manufacturer, and the mechanic, by means of the Copyright Laws, the registration of Designs Act, and the Patent Laws, in each of which cases where a monopoly is granted, a copy of the design or specification of the article to be protected, is deposited for the information of the public in some duly appointed repository, might not the Government, with equal justice and advantage, be asked to give to the person who discovered in a foreign country products fitted for and applicable to industries, be enabled to obtain a right of import from such country of the product which he had discovered, and of which he was the first and the true importer; and in consideration of such right being granted he might be required to deposit samples of the product, which could be deposited in a National Trade Museum. He never for

one moment contemplated the desirability or possibility of Government compelling manufacturers to deposit copies of the works they produced. In thanking the members for the full discussion which they had given his paper, he would add that his object in writing it would be fully attained if the interests which the Society was established to promote, could be advanced one step by the adoption of any of the suggestions made in the course of the discussion.

ROYAL SCOTTISH SOCIETY OF ARTS.

FORTY-FOURTH SESSION. THIRD MEETING.

The Society met in their hall, 117, George-street, Edinburgh, on Monday, the 12th Dec., at 8 o'clock, p.m. Charles Cowan, Esq., of Logan-house, President of the Society, in the chair.

The following communication was made:—"Exposition of the late Researches on the Cohesion Figures of Liquids," by Thomas Thethill Wright, M.D., &c., with illustrations by the oxy-hydrogen light.

Dr. Wright stated that, on being requested to give one of the "Special Discourses to the Society of Arts," he had chosen the subject of the "Cohesion Figures of Fluids," as he was desirous of bringing before the practical men assembled at the meeting the remarkable researches of Tomlinson, as well as observations made by himself in the same field. The lecturer then proceeded to give a very full exposition of Tomlinson's discoveries, with numerous carefully executed drawings of the cohesion figures of various oils and other fluids when dropped upon surfaces of water and other liquids, figures which have already been exhibited by their discoverer at the Society of Arts in London in his paper read before it. Dr. Wright then proceeded to describe two new classes of cohesion figures discovered by himself:—1st. Figures produced on perfectly clear and freshly split surfaces of mica; and 2nd. Figures produced by drops of fluid on surfaces of mica or glass, when connected with the poles of an induction-coil. He showed, by the oxy-hydrogen lantern, on a screen twelve feet in diameter, images of both these classes of figures, as well as numerous drawings of microscopic figures which were too small to appear on the screen. The mica figures were produced by placing a large drop of fluid (sulphuric acid, nitric acid, tinctures of iodine, henbane, vegetable infusions, and a great variety of animal fluids and mixtures of them) on the surface of the mica, and gently breathing on them, when the cohesion figures instantly developed themselves in an infinite variety of forms. Those shown on the screen consisted of an infusion of the extracts of belladonna, senna, and hemlock, and of healthy urine, urine containing bile, and urine containing albumen. These figures were rendered visible, developed as it were, by dusting them with a powder-puff containing hair-powder or the finest lamp-black. Dr. Wright pointed out that all these figures presented a distinctly bisymmetrical form, and imitated, with remarkable clearness, the forms of various microscopic algae and diatoms; while some of the images of urine, developed with carbon, in addition to their branching forms, were minutely veined, so as to resemble the finest specimens of agate. The second class of figures—the electric cohesion figures—differed entirely with the fluid used, the surface on which it was placed (whether glass or mica), the intensity of the electric current, and the pole (whether positive or negative) by which the fluid was electrified. Very splendid and large figures were made on chemically

* In producing the electric cohesion figures, a plate of brass is laid on the table, and covered with a sheet of black paper dripping in a solution of chloride of calcium; on this the glass plate is laid, and in the centre of the glass plate the minute drop of fluid to be electrified. One pole of the induction coil is connected with the brass plate, the other with the drop. The figures instantly shoot out as soon as the induction coil break is set in motion.

clean plate-glass by powerful induction coils. But the greatest variety of figures occurred when the thinnest microscopic glass and mica were employed, with a small induction coil, giving a spark of about a tenth of an inch. The electric figures on mica differed entirely from those on glass; and those on mica freshly split from those on mica washed, heated, or exposed to the air; in fact, the slightest change in the character of the fluid, or the surface on which it was dropped, resulted in the production of difference of figures. The electric figures projected on the screen imitated curious forms and species of Ulva, Ceramium, Delesseria, and finely-branched lycopodiums. Dr. Wright stated that in these cohesive figures of Tomlinson and himself, the pattern-designer possessed a source of infinite diversity of form, free from the stiffness of the designs furnished by the kaleidoscope of Brewster. Many of the figures in mica glowed with all the gorgeous tints of the soap bubble.

At the close of the discourse, his grace the Duke of Argyll moved a special vote of thanks to Dr. Wright for his admirable exposition, which was seconded by Dr. Stevenson Macadam, and unanimously agreed to.

The Society then proceeded to private business.

DUBLIN INTERNATIONAL EXHIBITION, 1865.

It is eminently satisfactory to learn that this enterprise, undertaken by Irishmen, actuated solely by patriotic motives, will fully realise the hopes of its promoters. The preparatory arrangements are in a forward condition, and the promises of support from home contributors ensure the success of the Exhibition.

Continental exhibitors have come forward with alacrity, and from them large contributions are expected. From France there will be a magnificent collection of bronzes and goldsmiths' work, of silks and laces; it is even hinted that the *Gobelins* and *Sèvres* will not be unrepresented. Austria will send specimens of all those beautiful manufactures which attracted so much attention in 1862. Italy intends to surpass herself; filigree work from Genoa, ornamental metal work from Milan, mosaics from Florence, and cameos from Leghorn, will attest the renewed industrial activity of this rising country. A display of sculpture, equalling, if not surpassing, the attractive collection sent in 1862, is promised from Rome. The show of manufactures from Belgium will be in proportion to the extent of her important industries. Countries in the North of Europe will be chiefly represented by works of Fine Art, of these special details will be given hereafter.

One special feature of this Exhibition, not attempted on any former occasion, will be an international display of musical instruments. A large hall, specially designed for concerts, and capable of seating 3,000 persons, has been devoted to this purpose. In it the instruments of all nations will be collected, and daily performances will take place during the continuance of the Exhibition. Exhibitors will therefore have the advantage, not only of showing their works, but also of having them tested under most favourable circumstances, and music as an art will be added to the other attractions of the Exhibition.

The following foreign committees and agencies have already been nominated:—

AMSTERDAM.—*Commissioners*—Mons. C. E. Vaillant and Dr. J. A. Van Eyck.

BERN.—*Commissioner*—Professor Vogt.

BRUSSELS.—*Committee*—M. Fortamps, Senator; M. Corr Vander Maeren; and M. Jules Kindt, Industrial Inspector, &c. *Secretaries*—M. Dulieu; M. C. J. Clerfeyt, *Assistant*. Office, 80, Avenue de la Toison d'Or.

CHRISTIANIA, NORWAY.—*Committee*—J. R. Crowe, Esq., C.B., Her Majesty's Consul, and M. E. Tidemand.

CONSTANTINOPLE.—Edward F. Ede, Esq.

COPENHAGEN.—Professor Hømmell.

DUSSELDORF.—*Commissioners for Prussia*—Herr Alexander Von Sybel, Elizabeth Strasse; William Mulvany, Esq.; and M. Adolph Tidemand.

FLORENCE.—*Committee*—Baron Ricasoli; Marchese Ginori; Cav. Cesare Conti, Pres. Chamber of Commerce; Cav. Niccoli Antinori, Sec. Academy of Fine Arts; Charles Lever, Esq., H.B.M. Consul for Spezia. *Secretary*—Signor P. L. Barzelotti, Advocate. Office, Chamber of Commerce, Florence.

FRANKFORT-ON-MAINE.—*Commissioner*—Herr Peter Bender, Market-place.

MILAN.—*Committee*—Cav. Antonio Calmi, Sec. Academy of Fine Arts; Comm. Giulio Curioni, Sec. Lombard Institute; and Cav. Carlo Pisanì, Sec. Chamber of Commerce.

NUREMBERG.—Dr. Beeg, Director of the Industrial Museum.

PARIS.—*Commissioners*—M. Savoye, M. Cappe, and M. S. Ferguson, file (special for Class C). *Secretary*—M. Tolhausen. Office, at the Palais de l'Industrie, Porte No. 1, Champs Elysées.

ROME.—*Commission*—Baron Comm. Pier Domenico Costantini Baldini, Minister of Commerce, Fine Arts, and Public Works, *President*; Cav. Luigi Cusi, *Vice-President*; Comm. Luigi Grifi, Sec. Ministry of Commerce, &c., *Secretary*; Comm. Tommaso Minardi, Inspector of Public Pictures; Comm. P. Ercole Visconti, Commissary of Antiquities; Comm. Pietro Tenerani, Director of the Pontifical Museums and Galleries; Comm. Luigi Poletti; Cav. Francesco Podesti; Cav. Giovanni Batista de Rossi; Comm. Virginio Vespignani; Comm. Niccola Cavillieri S. Bertolo; Cav. Prof. Benedetto Viale Prelà; Prof. Francesco Pratti; Cav. Valerio Trocchi, President of the Chamber of Commerce; Prof. Clement Luigi Jacobini; and Cav. Prof. Giuseppe Ponzi.

STOCKHOLM.—*Committee*—T. O. Hunt, Esq., H.B.M. Consul, and Count Rosen.

TURIN.—*Committee*—Comm. Devincenzi, Royal Museum of Industry; Hon. H. G. Elliott, H.B.M. Ambassador; Professor Manna, formerly Minister of Agriculture, &c.; Comm. Matteuci, formerly Minister of Public Instruction; Cav. G. B. Tasca, President of the Chamber of Commerce; Cav. Pio Agodino; Cav. Luigi Rey; and G. P. Jervie, Esq., *Acting Secretary*. *Assistant*—Signor Antonio Fassini. Office, at the Royal Industrial Museum.

VIENNA.—*Commissioner*—Herr Heinrich, Sec. Society of Arts, Tuchlauben, II.

INDUSTRIAL EXHIBITION FOR MARYLEBONE.

A meeting was held on the 13th Dec., at the Marylebone Court-house, Marylebone-street, for the purpose of getting up a Working Classes Industrial Exhibition in that populous and wealthy borough.

Sir ROUNDELL PALMER, Attorney-General, who occupied the chair, observed they must all feel anxious that opportunities should be given to the promoters of industrial pursuits and the fine arts among the working men, to have their works presented before the public in a manner as advantageous as those of others, and perhaps more so, especially as they had now had resources, by means of these exhibitions, which ought to enable them to compete with advantage with any other class in this metropolis. The language held in a resolution passed on the 14th of September, declaring that exhibitions of this kind were eminently calculated to promote inventions and industrial arts, did great good, by rousing the public mind to their advantage. Exhibitions of this kind showed clearly what could be done even under great disadvantages. The credit of the works of the artisans, or working classes, had hitherto too frequently been given to the employers instead of the artisans themselves, and it was therefore exceedingly desirable to give the latter an opportunity of receiving the rewards due to their success. It was clear

that such industrial exhibitions promoted inventive arts, and ought therefore to be encouraged by every possible means. He had been told that some anxiety was felt because the exhibitors at these exhibitions had no the same protection afforded them for their inventions as was given at the great exhibitions. Now to afford that protection was a just principle. Whether there was at that moment any practical objection to such a course he could not take upon himself to say, but he would do the best in his power to remove that evil, and he should be prepared to give due and just protection to them, and in a manner by which they would be enabled to take out their patents as if no publication or exhibitions of this kind ever existed.

The Rev. EARDLEY WILMOT, one of a deputation from the Central Committee, said they lived in an age of progressive improvement in arts and sciences, and especially among the working classes; and he would remind them that one of the greatest improvements of the day—namely, the system of railways—was the invention of a labouring man, Mr. George Stephenson. As regarded the proposed Industrial Exhibition, there was no doubt whatever that, socially, morally, and artistically, it would be of great advantage to the working classes, whose ingenuity and industry were now used, generally speaking, for the advantage of employers. With respect to the movement itself, they had held already many district meetings, formed a general committee, and appointed a treasurer to receive subscriptions, in order to form a guarantee fund. They were in treaty for the Polytechnic Institution, and hoped by the end of next March to have an Exhibition open for a few months, which would be of the greatest possible advantage.

Mr. MORRELL said no less than £244 was already subscribed by the working men themselves as a guarantee fund. As to a protection being given to exhibitors, their learned chairman told them he would do all in his power to obtain it; and they had already a similar promise from the Commissioner of Works. Such a protection was granted at the Great Exhibition, and he was sure Lord Palmerston would afford the same to the working classes.

Mr. HOWE moved, and Mr. MORRIS seconded, the first resolution, "That this meeting cordially approves the proposed Industrial Exhibition for the working classes for the borough of Marylebone, and pledges itself to use every exertion to carry it out."

Mr. GRAHAM would be glad to render every assistance in his power for the success of the Exhibition, and had great pleasure in supporting the resolution.

Mr. HURTON moved, and Mr. PINNER seconded, the next resolution:—"That a district committee, to be called the Court House Committee, be formed out of this meeting, who shall arrange their own place and time of meeting; and depute three of their members as representatives at the Central Committee, which meets every Friday evening at the Working Men's Club."

Mr. NICHOLAY supported the motion. He had taken an interest in other Exhibitions, and especially in that of North London, which was an eminent success in every particular, and realised, after paying all expenses, upwards of £1,000, which was now in the hands of the committee, and would be devoted to some useful public object.

Fine Arts.

ROYAL ACADEMY.—At the recent examination of the Royal Academy silver medals were awarded to Mr. Thomas Davidson, for his painting from the life; to Mr. Frederick George Oakes, for the best copy in oil colours; to Mr. Claude Andrews Calthrop, for the

best drawing from the life; to Mr. Richard Lincoln Alldridge, for the best drawing from the antique; to Mr. James Griffiths, for the best model from the antique; to Mr. Sydney Williams Lee, for the best architectural drawing; to Mr. Horace Henry Cauty, for the best perspective drawing; and to Mr. Richard Phené Spiers, the travelling studentship for one year, for architectural design. —On Friday evening, 16th December, at a general meeting of the Royal Academy, two associates were admitted to full honours to fill the places left vacant by Thomas Dyce and Sir Watson Gordon. The choice fell upon Mr. Thomas Faed and Mr. John Calcott Horsley. The vacancy by the death of David Roberts has not yet been filled up.—Mr. Solomon Hart, R.A., has been elected librarian of the Royal Academy, in the place of Mr. Pickersgill, R.A., resigned.

THE QUEEN'S NEW CAMEOS.—The Queen has commissioned Signor Saulini, of Rome, to execute a number of cameos in shell, representing the busts of her Majesty and the late Prince Albert. Some of these beautiful works, exquisite in conception and in art, have arrived in London, where they will be set in gold, and presented, it is said, as others have been, either to members of the Royal family or to distinguished ladies, personal friends of the Queen. One not uncommonly meets with German ladies who wear on the left shoulder decorations presented by their sovereign, and perhaps her Majesty in this touching way has instituted an order to perpetuate the memory of one in every manner so worthy of her deep affection. The likeness of Prince Albert is inside, that of the Queen outside, and both are admirable specimens of the artistic skill of Saulini. Already by command of her Majesty six cameos have been cut in pietra dura (onyx), four in shell, and five more in shell have yet to be completed. Those in the pietra dura require long and patient labour, each occupying from three to four months in completion.

RE-ARRANGEMENT IN THE LOUVRE.—Those who have not visited Paris for a year or so will find many alterations. In the first place, there are the new galleries containing the works of the French School, the extensive Campana and Sauvageot collections, and the great Etruscan room, of which mention has already been made in the *Journal*. More recently two large apartments in the basement of the New Louvre have been opened to the public, one containing the statues and busts belonging to the Campana collection, which, however, are very unfortunately placed with respect to the light, the vaulting being low and flat, and both sides pierced with numerous windows. This great defect is not felt in the companion gallery, which is now occupied by the electro galvanic reproductions of Trajan's column, which were referred to in a cursory manner in the report of a visit to the works of M. Oudry, at Auteuil, which appeared in the *Journal* some months since. The whole of these extraordinary reproductions may now be seen and examined conveniently. These beautiful casts have been set up in their proper spiral order on six sections of a column, each about twenty feet in height, with the exception of the four sides of the square basement which stand against the walls of the gallery; every portion is well exhibited, and the whole forms an admirable study. We understand that a complete and illustrated description is being prepared by command of the Emperor. The portion of the great picture gallery built by Louis XIV. is now completely demolished, and its reconstruction, in harmony with the beautiful work of Henry IV., is about to be commenced. Lastly, the administration is at the present moment considering the question, or rather trying the experiment, after the example of the Tribune of Florence, of introducing sculpture into the picture galleries. In the centre of the apartment known as the Salon Carré, the square room in which are placed the *chefs-d'œuvre* of the collection, has been placed the famous "Diane à la biche;" at the door which leads from this room into the great gallery are a

"Venus" and a "Bacchante;" and at the end of the small gallery, which contains a collection of the works of the Italian School, stands the "Diane de Gabics." There is no doubt that the effect of the statues is good, but the removal of such works causes a terrible blank in the sculpture gallery.

Manufactures.

GAMBOGE.—At a meeting of the Pharmaceutical Society, on December the 3rd, Mr. Daniel Hanbury read a paper "On the Botanical Origin of Gamboge," by which it appears that the exact botanical origin of gamboge has long been involved in obscurity, for though it was known to be a plant of the genus *Garcinia*, the species had never been determined. Hermann, who lived in Ceylon in the 17th century, referred the origin to two plants—one now known as *Garcinia Morella*, the other as *G. Cambogia*—and it is stated by Mr. Thwaites that the former yields a good form of the drug, but not the latter. Gamboge, however, is not an export from Ceylon, but is produced in Siam, a country as yet but little known to botanists. Whether gamboge was obtained from the same tree in Siam as that which yielded it in Ceylon could only be decided by the examination of good botanical specimens. Some years ago, Dr. Christison received from the Messrs. D'Almeida, of Singapore, specimens of *Garcinia* cultivated by them which had been brought from Siam as the true gamboge tree. Dr. Christison found the plant to be nearly allied to *G. elliptica* of Wallich, but differed by having pedicellate instead of sessile male flowers. Recently the author has received specimens from the Messrs. D'Almeida, and has compared them with a variety of descriptions, figures, and specimens, the result of the comparison confirming Dr. Christison's observation that but for the pedicellate flowers the plant bore a strong resemblance to *Garcinia elliptica*, and, further, came equally near *G. Morella* of Desrousseaux. Under these circumstances he sent specimens to Mr. Thwaites, in Ceylon, for his opinion, who replied that he believed the specimen to be a form of *G. Morella*, scarcely differing from the Ceylon type, except in having pedicellate in place of sessile flowers. The author and other botanists, therefore, now describe the gamboge-yielding plant under the following names and synonyms:—*Garcinia Morella*, Desrousseaux; var. *pedicellata*. Syn.; *G. Morella*, Desrousseaux; *G. elliptica*, Wallich; *G. Outta*, Wight; *Hebradendron Cambogioides*, Graham; var. *β pedicellata floribus masculis pedicellatis*. The number of trees now growing on the plantation of Messrs. D'Almeida is twenty-eight. They are from thirty-five to fifty feet in height, and the largest has a circumference of three feet. They grow very luxuriantly on the side of a hillock without any attention. Gamboge has been at times extracted from them, but only as a matter of curiosity.—Professor Bentley said that Mr. Hanbury has now supplied the last link wanting in the chain of evidence to prove the true botanical origin of gamboge. He believed that there was no specific difference between the gamboge trees of Siam and Ceylon; they were simply varieties, depending probably upon soil and cultivation.

CHURCH BELLS.—The new belfry of the church of St Germain-l'Auxerrois will soon receive a set of chimes similar to those for which Strasburg, Dunkirk, Bruges, &c., are celebrated, but with the improvements suggested by the progress of modern mechanical art. M. Collin, who is entrusted with their execution, has rejected all the cumbersome old contrivances which exclude the possibility of playing several tunes except at an enormous cost. While the cylinder or barrel which works the chimes at Bruges, for instance, cost 60,000*fr.*, M. Collin's barrels will cost only 250*fr.* each, so that as every tune requires a barrel by itself a great variety of tunes will be

obtained at a very trifling cost. Instead of the enormous weights attached to the works under the old system he employs Lenoir's gas-machine as a motive power, whereby he forces air into a reservoir so as to produce a pressure of 2½ atmospheres. The air thus accumulated passes into a series of bellows, replacing the levers of the old system, and thus the artist who sets the chimes in motion finds an instrument as easy to play as a piano. The chimes will consist of forty bells, and will play two different tunes daily—one at two p.m., and the other at eight p.m.

PORTSMOUTH BLOCK MACHINERY.—A writer, under the signature of "J. B.," in a letter addressed to the *Times*, says:—"In your impression of the 17th inst. is a notice of the collection of Naval Models at South Kensington Museum, in which the block machinery at Portsmouth is said to have been 'invented by Sir Isambard Brunel, for the use of the Government, early in the present century,' and it is said that 'this invention was rewarded liberally by the Government.' Sir Isambard Brunel did not invent, nor did he ever claim to have invented, the block machinery which he had a share in setting up at Portsmouth. The original invention, or series of inventions, was by two men, father and son, each named Walter Taylor, natives of Southampton. The beginning was rather more than a century ago, and was made by the father, who had been at sea, and had been practically impressed with the inefficiency of the blocks in use in his time. After a time they took out a patent for part of their inventions, and subsequently a second patent. These included friction wheels and circular saws, both of which we owe to the Taylors. During the continuance of their patents they, under contract, supplied the Government with blocks for the navy, and for some years theirs were the only blocks used in the Royal navy. When, towards the close of the last century, their patents expired, they wished to obtain an extension of them, but the Government objected, and decided on setting up the machinery for themselves. Mr. Walter Taylor, the son, who was then making his blocks at the Wood Mills, South Stoneham, near Southampton, generously offered to the Government every facility for the purpose. The Government employed two clever young men to set up the machinery—one of whom was Mr. (afterwards Sir) Isambard Brunel, and the other Lieutenant (afterwards General) Bentham, R.E. With the benefit of Mr. Taylor's explanations these two young men examined his machinery, and then proceeded to set up machinery on the same principle at Portsmouth. Having the resources of Government to back them they improved the details of the machinery, using for it steam power instead of water power, by which Mr. Taylor's mills were worked; but in every essential point the block machinery at Portsmouth is the invention of the Messrs. Taylor. General Bentham's share in the improvements has been forgotten as much as the Messrs. Taylor's original invention. Some years ago the specifications of the patents were printed in the *Builder* newspaper, and they will enable any one of a mechanical turn of mind who wishes to ascertain how far Messrs. Brunel and Bentham were indebted to the Messrs. Taylor to do so easily. The originality of the invention was more than once publicly claimed for the Messrs. Taylor during the lifetime of Sir I. Brunel—once in your own columns—and the claim was never contested by him or by General Bentham, although, I believe, General Bentham's widow objected that too little credit had been assigned to her husband. Would it be quixotic to hope that Government, which has so greatly benefited by the invention of the Messrs. Taylor, would, at the South Kensington Museum, give some intimation of their obligations to them?"

PETROLEUM AS FUEL.—Mr. B. H. Paul, in a communication to the *Chemical News*, says:—"Some months ago considerable interest was excited by the announcement that very remarkable results had been obtained in America by the application of petroleum as fuel for the boilers of steam vessels, and so much importance was attached to the subject, that a commission was appointed by the

Government of the Northern States to inquire into this application of petroleum. The report published by the commission, as the result of their labours, was calculated rather to excite curiosity than to afford satisfactory information, and they have not, so far as I am aware, made public any further data which would afford a means of arriving at an opinion on the subject. The proposal to use petroleum as steam fuel in ships became, almost of course, a subject of consideration in this country, and an idea prevailed that this invention might possibly supersede in importance all the recent improvements connected with the naval or mercantile marine. It was anticipated that not only naval warfare, but even navigation itself, might be completely revolutionised by this invention. It was reasonable enough that a project put forward with such pretension, as was the case in respect to the use of petroleum as fuel for steam vessels, should be considered in a country where every improvement relating to steam navigation is of high importance; but it is surprising that no one should have disabused the public mind of the erroneous impressions produced by the statements as to the use of petroleum as fuel; for to any one conversant with the composition and characters of petroleum, as compared with coal, this proposed application of it was obviously absurd. Little has been heard of this project until some days ago a notice appeared in the *Times*, under the head of 'Naval and Military Intelligence,' stating that experiments are being conducted at the Woolwich Dockyard, with the view of testing the capability of petroleum to supersede coal and other fuel on ship-board, &c. In this notice it was stated that the oil was so utilised 'as to be equal for steam purposes to five tons of coals.' How much of the oil was equal to five tons of coals was not stated, but it may be fairly supposed that any one unacquainted with the subject would infer that one ton of oil was meant. Now, what are really the facts of the case as to the comparative advantages of petroleum and coal as fuel? In the first place, one of the chief alleged advantages of petroleum over coal, was that it would lie in a small compass and make less demand upon space and tonnage than coal does. Since with petroleum in the place of coal, two-thirds of the space now required for fuel in a steam vessel would be saved, steam ships might keep at sea three times as long as at present. Then, coal depôts would be unnecessary for steam packets on the longest lines of ocean navigation; and since no stokers would be needed in using petroleum, a whole army of employes might be dispensed with. Now, the specific gravity of coal is from 1.24 or 1.44 to 1.6, while that of petroleum is from 0.800 to 0.850, consequently the weight of a cubic foot of these materials would be, respectively, about as follows:—

	lbs.	lbs.	lbs.
Coal	77.4	90	100
Petroleum...		50	53

But, since petroleum, being liquid, lies in a more compact manner than coal, in estimating the spaces occupied by these materials, allowance should be made for the interstices or empty spaces between the lumps of coal. Taking this as amounting to one-third of the whole bulk of a heap of coals—which is a liberal allowance—the contents of a cubic foot would be as follows:—

	lbs.	lbs.	lbs.
Coal	52	60	70
Petroleum	50	53	—

So that the spaces occupied by equal weights of coal and petroleum would be about as 1 is to 1.2 or 1.4. Then the relative heating power of equal weights of coal and petroleum would depend upon their respective chemical composition, which may be compared as follows for 100 parts:—

	Coal.	Petroleum.
Carbon	83	85
Hydrogen	5	15
Ash, &c.	12	—
	100	100

Accordingly, the relative heating power of equal weights of coal and of petroleum would be in the following ratio:—

	Coal.	Petroleum.
Calorific power	1.02	1.50

And the spaces occupied by quantities of petroleum and of coal, having equal heating power, would be in the ratio of 1 to 1.16. This difference in favour of petroleum is in itself too small to admit of any advantage being gained in regard to stowage, and it is more than doubtful whether there be any other advantageous difference between petroleum and coal for fuel. It must also be considered how far the difference between the prices of petroleum and coal would have the effect of neutralising the above, or any other advantage to be gained by the use of petroleum as fuel. The price of petroleum varies from £15 to £20 per ton, while that of coal used for steam-vessels is under £1 per ton at any part of the British coast, and even at the coaling stations in the East it does not exceed £2 10s. to £3 10s. per ton. These considerations alone appear to me to decide the question as to the practicability of using petroleum as steam fuel under any possible circumstances, for even in the case most favourable for the comparison of petroleum with coal, the cost of equal quantities of heat produced from these materials, would be in the ratio of £15 to £4. In addition to this, the highly inflammable nature of petroleum must be considered. Its storage on board a ship would require the use of air-tight vessels, and even then there might be considerable risk of the production of explosive mixture of the petroleum vapour and air. But what would be the condition of a vessel of war provided with petroleum as fuel, if a shot penetrated the vessel containing the petroleum, and allowed it to escape in proximity to the boiler fires? Taking all these circumstances into consideration, I think there cannot be any doubt as to the entire fallacy of supposing that petroleum can be substituted for coal as fuel; and though this conclusion is sufficiently evident from the data I have adopted as to price, &c., it must also be remembered that the tendency is rather to a rise in the price of this commodity than otherwise."

Commerce.

IMPORT OF COTTON.—In the first three quarters of the present year, raw cotton of the enormous value of £56,334,266 has been imported into this country, an amount equal to the sum paid for the cotton import of the entire year 1863, and far exceeding the value of the cotton import of any previous year. The value of the cotton import of the year 1860 was but £35,756,889, and the quantity received for that sum exceeded 12,000,000 cwt. Only half that quantity has been received in the first nine months of 1864 for the far larger sum first mentioned. The quantity received in the first ten months of the year was 3,076,073 cwt. in 1862, 4,226,127 cwt. in 1863, and 6,146,796 cwt. in 1864. In the first ten months of 1862 India sent us 2,190,604 cwt., and Egypt 429,464 cwt.; in 1863, India 2,611,985 cwt., and Egypt 661,104 cwt.; and in 1864, India 3,355,747 cwt., and Egypt 892,419 cwt.

PLUMBAGO ON LAKE SUPERIOR.—Another extraordinary mineral discovery has been made on Lake Superior, being no less than a rich mine of plumbago (graphite). It was found on the tract of the Marquette Silver Mining Company, and it is said that Prof. Cassels, of Cleveland, who has made an assay, pronounces it the best plumbago he ever saw, and if it is plentiful, the mine is worth more than any gold mine in the country. Capt. Sweet, who is familiar with the ground, says the mine is very rich. There are several mines of very inferior graphite found in North America, the product of which is used in the

manufacture of crucibles, and for other uses in manufactures. None of it is fit for pencils. The Silver Lead region of Lake Superior must be a wonderful place if all the "discoveries" located on it amount to anything. Lead, silver, gold and plumbago appear to put the discoverers in doubt as to which they shall mine for first. Iron is close by and copper not far off. All that is needed now to complete the discoveries is tin.

BONNETS.—In the south-eastern part of Massachusetts 12,000 persons are employed in bonnet factories, and they send away annually nearly 8,000,000 bonnets and hats

Colonies.

NEW ZEALAND.—A considerable number of measures have engaged the attention of the Council of this Province (Hawke's Bay), not the least important of which is one to re-appropriate the loan of £60,000 agreed to in a former session. The appropriation now stands as follows;—£30,000 for the purchase of land from the natives; £10,000 for immigration; £1,000 for a lighthouse for Napier Port; £5,000 for a bridge over the Ngarurovo; £7,000 for the completion of the main trunk line, known as the Te Aute-road; and £7,000 for harbour purposes; the last item not to be expended until an opinion has reached us from a competent authority in England. With reference to the item of £30,000, appropriated out of the loan for the purchase of native lands, it was stated in the Provincial Council, by Mr. Ormond, one of the members of the Executive, that Mr. McLean, in his capacity of Native Land Purchase Commissioner, was sanguine of being able shortly to purchase some good lands from the natives. Should this hope be realized, the land will be set aside for agricultural purposes, so as to make the province more attractive as a field for immigration.

ANOTHER RAILWAY IN NEW ZEALAND.—An offer has been submitted to Government to make, as soon as the state of the country would allow, a railroad to Wanganui. It is to be a single line, capable of carrying an engine of not less than fifteen tons, but the offer does not include stations or rolling stock, the line to be given up piece by piece as completed. The payment asked for is land at the rate of an acre and a half for every pound sterling expended by them in making the railroad up to £4,000 per mile, that is to say, that each mile of railroad will cost 6,000 acres of land, but cannot cost more. It is proposed that the contractors should not take the whole of the land adjacent to the railway, but take it in blocks alternately with the Government.

NATAL.—The *Natal Mercury* says:—"The tract of land now known as No-man's-land is about to lose that familiar and expressive name. That district has a frontage of 35 miles to the sea, a depth of 130 miles to the mountains, and an area of 5,000 square miles, or three millions of acres. About one-third of this, that is, the portion near the coast, belongs by right and cession, and it is now proposed to be so by law, to this colony. This little slice of ours is made somewhat rugged by the existence of twenty streams that flow into the sea, and the report likens it to the country between Durban and Pinetown. If this be the case we see no reason why it should not be a most valuable site for the settlement of European agriculturists. The climate of this region resembles that of Natal, being, however, slightly modified by its greater distance from the equator. There is one misfortune, however, connected with it—a population already resides there, various small tribes of Kaffirs, numbering in the aggregate 10,000 people.

AUSTRALIAN COINAGE.—The quantity of gold-dust imported into the Sydney branch of the Royal Mint, from the 1st of January to the 16th of September, 1864, amounted to 552,885 ounces. For the corresponding period of the year 1863, the receipts were 326,014 ounces.

The coin issued during the present year had been 2,006,000 sovereigns against 766,000 sovereigns and 558,500 half-sovereigns during 1863. Total value, £995,250. The quantity of gold received from Melbourne and New Zealand at the Mint accounts for this large increase in the receipts of the year notwithstanding the serious falling off in the yield of our gold-fields.

Obituary.

MR. JOHN FOWLER, of Leeds, died on the 4th Dec. from the result of an accident while hunting. This distinguished pioneer in the application of steam power to the cultivation of the soil, was born at Melksham, in Wiltshire, in 1825, his father being a banker and merchant in that town. John Fowler early devoted his attention to mechanics. He was originally engaged in commercial pursuits, but so strong was his love of mechanics that he left the counting-house and entered the engineer's workshop. He was apprenticed to an engineering firm in the North of England, after which he went to the Orwell Works at Ipswich, where, in conjunction with Mr. Fry, of Bristol, he first made experiments in the application of steam to the drainage of land; and it was whilst he was engaged at Messrs. Ransomes and Sims' works that he made his first experiment in steam ploughing. It was also at these works that most of his engines and tackle were made, up to the time when he won the Royal Agricultural Society's prize of £500, at Chester, in 1853. While carrying out draining operations, John Fowler's attention was first directed to the cultivation of the soil by the aid of steam; and at the Royal Agricultural Society's Show at Carlisle, he arranged with Mr. Smith, of Woolston, to produce a steam engine and windlass for moving Mr. Smith's cultivator. The late Robert Stephenson, M.P., then warmly took up the subject of steam ploughing, and it was after this time that Mr. Fowler went to Leeds, where, in conjunction with the late Mr. Hewison, he erected the extensive works now in operation. Mr. Fowler, previous to erecting the works at Leeds, acquired the right to use almost all the patents for the application of steam power to the tillage of the soil; and since the establishment of the works at Leeds, a great many engines and tackle have been supplied for various parts of the world. The rapid development of the use of steam cultivation since 1859 is partly due to the fact that the war in America directed attention in Egypt and elsewhere to the extended cultivation of the cotton plant; and during the last two or three years the principal orders for steam cultivators have come from Egypt. Upwards of 300 of Mr. Fowler's apparatus are also at work in various parts of the United Kingdom, and his steam ploughs are in operation in America, Egypt, India, the Australian Colonies, and New Zealand, and on the Continent of Europe. For several years Mr. Fowler obtained the chief prizes offered by the Royal Agricultural Society of England at their competitive trials, and from most of the local societies, but it was the prize of £200 which he first received from the Highland and Agricultural Society of Scotland, to which Mr. Fowler attached the greatest importance, as he believed it led the way to the more general appreciation of the steam plough in England. At the last International Exhibition he received a medal for his steam plough and cultivator. Mr. Fowler was elected a member of the Society of Arts in 1855, and on the 30th January, 1856, at an ordinary meeting, read a paper before the members, "On cultivation by Steam; its Past History and Probable Prospects," which will be found reported in the 4th vol. of the *Society's Journal*, page 163.

Notes.

SOCIAL SCIENCE ASSOCIATION.—The Council of the Social Science Association have decided to hold their next meeting in Sheffield, in the autumn of 1865.

IMPROVED LEVEL.—At the meeting of the Institution of Civil Engineers, December 13, Mr. F. B. Doering exhibited and explained a level which, for readier adjustment, was supported upon a gimbal joint, instead of on parallel plates; and he stated that the plan was applicable to other surveying instruments. The method was similar to that adopted for a ship's compass, with the addition of vertical arcs, at right angles to each respective axis, which were clamped to each other and to the frame that was screwed on to the ordinary tripod stand. In the field, when using this instrument, however uneven the ground might be, the legs were put down in the most convenient manner, irrespective of level. The clamps holding the telescope rigid with the stand were then slackened, and the telescope set approximately level by hand. The clamping screws were then tightened, and the final adjustment effected by two tangent screws at right angles to one another, and connected respectively with each arc at the clamps. On moderately level and firm ground, it was not necessary to unclamp the joint of the instrument, as it might be set up approximately level in the ordinary way by the legs, and be brought to a perfect adjustment at once by the tangent screws. By dividing one of the arcs into degrees, the instrument might be used for measuring vertical angles, and thus the height of any point at a distance, required for checking, might be obtained. It was believed that, by this method, a level could be set up on sidelong, soft, or broken ground, with as much ease as on firm, level ground; and that, as none of the moveable parts were liable to become jammed, as in the parallel-plate system, a more perfect adjustment was practicable. A level constructed in this manner had been tried in wet weather and in high winds, and proved to be as steady as any instrument hitherto made.

GAS IN EGYPT.—On the evening of the 23rd September the city of Alexandria was lighted for the first time by gas, the works having been erected by a French company. The lamplighter is nightly followed in his rounds by a crowd of wondering Arabs, who insist that the marvelous blaze following the touch of his torch must be provoked by the will of a *genie*, or "djinn," as Mr. Lane would have us spell the familiar word of the Arabian nights. This improvement causes a great change in the habits of the place. Heretofore a municipal regulation had required everybody going abroad after nightfall to carry his own lantern, but this is no longer necessary.

PARIS INTERNATIONAL EXHIBITION 1867.—It is reported in Paris that the idea of erecting a huge building over the Seine is given up—which will astonish few persons—and that the building for the next Great Exhibition will be a Crystal Palace, erected in a new boulevard, extending from the Arc de Triomphe, at the top of the Champs Elysées, to the river. The building now projected is to be large enough to give every country as much space as it may desire. It is to occupy the central portion of the boulevard, only leaving space for a carriage-way and for pedestrians, and on the other for a railway, or probably an American tramway. It is proposed to erect a steam lifting pump on the bank of the river, to supply the requisite quantity of water for all purposes.

EXHIBITION OF DOGS IN PARIS.—An exhibition of this kind is announced to take place in May next. The administration of the Jardin d'Acclimatation has just obtained the permission of the Prefect of the Seine to hold the next exhibition of dogs in the Cours la Reine, between the Champs Elysées and the river, between the two bridges the Pont de la Concorde and the Pont des Invalides, and consequently in a much more accessible position for the general public than the gardens of the

Society in the Bois de Boulogne, where the first dog show took place last year.

Correspondence.

RADIAL LOCOMOTIVES, SPRING TIRES, AND WOOD WHEELS.

SIR,—In the discussion on my paper of Dec. 7th, Mr. Teulon said that, "all changes on railways must be made with great caution;" and here I agree with him, though possibly we may differ in our modes of verification as to tests. I think it quite possible to do it rapidly, as iron beams are tested to breaking by heavy loads, while possibly Mr. Teulon might be disposed to apply the test of time with an ordinary load, and so carry his experiment over thirty years or more. It is better to make a positive experiment than a negative one. With regard to my radial engine, positive experiments have been made with it during the last eighteen months, and a body of the most eminent railway engineers have experimented with it; and I am authorised to say that in the proceedings of the Institution of Civil Engineers, not yet published, on the occasion of a paper read by Mr. Cross, the engineer of the St. Helen's line of railway, my radial engine was approved of by Mr. Hawkshaw, Mr. Charles Hutton Gregory, Mr. Vignoles, Mr. T. E. Harrison, Mr. G. Berkeley, and others, without a dissentient voice. Mr. Teulon, in addition to being a member of the Council of the Society of Arts, is also a Director of the South-Eastern Railway, and Chairman of the Committee of Rolling Stock and Way and Works. It is, therefore, very important that he should be accurate in all his statements, but it is clear that he is not what the Americans call "posted up" in the early details of mechanism on the South-Eastern, and especially in the history of the wood wheels thereon. The first wood wheels were mine, and applied to some carriages built by me for the opening, when Mr. Baxendale was chairman. These wheels were composed of centres of cast iron discs, surrounded by two circles of fellies doweled together break joint, each row being four inches in depth, on which the tire was shrunk by heating and cooling in the absence of a machine for pressure. The results of these wheels were so satisfactory that I subsequently applied solid discs of radial timber to cast iron centres for the same line, when the tires were applied cold by pressure, being secured in their places by the retaining rings of Mr. Mansel. This arrangement of end timber was not so good as the side grain of the former wheels. The present mode on the South-Eastern is a circle of wood fellies, about an inch in thickness, placed between an iron wheel and the tire, but the tire is heated and cooled to apply it, and this is not desirable, cold pressure being the safest. The principle is, in fact, precisely the same as in my earlier wheels. The true plan, in constructing such wheels, is to bend a piece of straight-grained timber into the form of a hoop, and place it within a tire rolled with a front flange, forcing the wheel into it with the tire cold by hydraulic pressure, and then securing it with a flat ring at the back, sprung into a shallow groove. In this made the retaining rings and bolts may be dispensed with, and the whole structure much simplified, as shown in a specification of mine, older than that of Mr. Mansel, quoted by Mr. Teulon. But even when made in the best mode, there is a serious defect when the two wheels are rigidly fixed on one shaft, by the torsion of the axle on curves and irregularities of the rails, through the wood packing tends to lessen the mischievous vibration. And there is another defect, in the contingency of using wood not properly dried, which may occur when manufactured on a large scale. It is well known that ordinary road wheels, if they stand long in the sun in dry weather, get loose, and require soaking in water to tighten them. A number of wood railway wheels were sent to India, in which discs of wood were applied between tire and centre. When unshipped a Lancashire inspector described them as

"tumbling to pieces and the discs rolling up and down the beach like so many cheeses." There is another objection. If a tire bearing on wood gets loose, the wood will grind away as it revolves, and be spoiled. It was for this reason that I turned my attention to the desirability of getting rid of the wood altogether, and substituting an elastic hoop of tempered steel. The result of this has been thoroughly satisfactory. It is evident that the only value of the wood is as a cushion and not as a flexible spring, and that it cannot slip upon the tire to compensate for varying curves, and prevent torsion of the axle. But the flexible spring does permit of slip of the wheel within the tire to prevent mischievous torsion of the axle, and it does also permit of horizontal variation in the tread to prevent unequal bearing, with a positive flexible yield to absorb blows; while in the case of a loaded driving wheel it permits a certain amount of flattening on the tread and an absence of jumping, which is very favourable to increased adhesion. And as the tension cannot be excessive and cannot be increased in time of frost, there is no risk of bursting the tires, while they can be removed and replaced without taking the engine or carriage into workshops. The remarkable results obtained in increased durability only require to be widely known to ensure their adoption generally, and the more especially in countries where repairs are difficult, and durability, above all, desirable. The reduction of wear in the tire surfaces permits them to be made considerably thinner and consequently of better metal, and prevents that mischievous fly-wheel action resulting from wheels with heavy peripheries. Mr. Teulon's remarks on the possibility of incessant travelling by rail would be better corroborated by individual names, tabulated, and stating distances, how many days together, and for what period of time kept up, sex, age, height, proportions, complexion, temperament, &c., all given by a medical man. These would be statistical facts to set against the general impression of injury to health.—I am, &c., W. BRIDGES ADAMS.

Patents.

From Commissioners of Patents Journal, December 16th.

GRANTS OF PROVISIONAL PROTECTION.

- Agricultural produce, machinery for cutting, &c.—2970—R. Maynard
- Atmospheric air, purifying, &c.—2937—J. White.
- Bells—2956—J. Evans.
- Boats, propulsion of—2899—J. Macintosh and A. H. Thurgar.
- Boots, shoes, &c., apparatus for eyeletting—2957—M. F. Heinzmann.
- Bricks, machinery for making—2972—G. Axton and J. Leach.
- Bromine and bromides, obtaining—2948—L. Lelaler.
- Bubbles from soapsuds, apparatus for blowing—3047—W. E. Newton.
- Cannons, &c.—2947—R. W. Slevier.
- Carriage axles and boxes—3063—E. Partridge.
- Carriages, apparatus for indicating the time engaged, &c.—2978—J. Flnaud.
- Cigar of other materials than tobacco—2977—J. D. De Boulmbert.
- Clockwork—3033—W. E. Gedge.
- Coprolites, apparatus for washing—2936—T. Perkins.
- Cotton fibre, apparatus for separating from seed—3009—E. A. Cowper.
- Deep sea soundings, apparatus for taking—2980—A. E. Dobbs.
- Dye-stuffs, purple—2894—W. V. Wilson and J. A. Wanklyn.
- Engines, feeding of scribbling and carding—3007—G. Wallis and B. Cooper.
- Engraving, apparatus for—2941—P. E. Galfio and E. Zglinicki.
- Feathers, &c., metallic ornamentation of—2944—W. Clark.
- Fibrous materials, machinery for combing—3066—W. Tongue.
- Fibrous substances, fuel, &c., presses for—2707—G. Ashcroft.

- Fibrous substances, opening and scribbling—2921—P. Garnett.
- Fire-arms, breech-loading—2907—J. Leetch.
- Fish preparing and potting the roes of—2986—J. Banger.
- Fuel, combination of materials to be used as—2852—A. Wall.
- Furnaces, condensing and collecting products volatilised in—3035—W. T. Watts.
- Fuzees—3015—C. W. Lancaster.
- Gas, apparatus for heating and cooking by—3013—R. A. Brooman.
- Gas, escapes of, apparatus for indicating, &c.—2984—M. Henry.
- Gas, regulating the supply of—3039—J. Keeling.
- Heavy bodies, trucks or carts for carrying and elevating—3031—H. Lamplugh.
- Hooped skirt, manufacture of—2760—A. V. Newton.
- Hydraulic presses—2942—E. Cottam.
- Hydro-beer pumps—2968—W. Jackson and W. Glaholm.
- Letters, balances for weighing—2885—W. Clark.
- Liquide, method of cooling—8923—F. Mills.
- Marine steam boilers, construction of—2565—W. E. Newton.
- Marmalade, preparation of—2938—W. Keiller.
- Metals, obtaining dense and flawless castings of—2831—G. Bell and R. Luthy.
- Mills for grinding grain—3025—J. Goodier and T. Lee.
- Minerals, machinery for cutting—2962—W. E. Carrett, J. Warrington, and J. Sturgeon.
- Motive power, apparatus for generating—2803—W. Clark.
- Paper, manufacture of—2963—J. R. Crompton.
- Pipes for smoking—2952—T. B. Laws.
- Pumps—3005—T. W. Gray.
- Railways, diminishing wear and risk on—2764—W. B. Adams.
- Railways, permanent way of—3055—J. Livezey and J. Edwards.
- Railways, signalling and giving alarm on—2767—J. Henshaw.
- Railways, switches or points for—2950—T. Knowles.
- Reaping and mowing machines—3043—W. J. Burgess.
- Rice, apparatus for cleaning—3027—J. Yearley and E. Timbrell.
- Roofs, walls, &c., construction of—2847—R. W. Wilton.
- Sewage, deodorising and utilising—2832—G. E. Noone.
- Shafts, reducing the friction of—3003—M. J. Roberts.
- Ships, compound for coating the bottoms of—3049—A. D. Hall.
- Soap, machinery for cutting into bars—3061—A. V. Newton.
- Spinning machinery, giving pressure to the drawing rollers of—2982—J. McIntosh.
- Steam boilers, apparatus for feeding—2940—L. Valant.
- Steam boilers, feeding—2988—E. M. Shaw.
- Steam boilers, generating steam in—2976—A. Wheatley.
- Steam engines—3011—J. France.
- Steam engines and rotary pumps—2960—T. Greenhalgh.
- Table covers—2946—W. Ward.
- Textile fabrics, preparing to be dyed for packing—2964—J. Smith.
- Umbrellas, parasols, and sun-shades—3037—J. Stephenson.
- Ventilating cupola chandeliers—2934—F. Sang.
- Wadding, &c., manufacture of—2709—E. Pilkington.
- Warming and ventilating apparatus—2932—J. Kissack.
- Wool, separating or recovering the fibres of—2958—J. Rowley.

Announcements by the Council.

ART-WORKMANSHIP PRIZES.

The Articles sent in competition for the Art-Workmanship Prizes are now arranged for display in the Society's Great Room, and the Members of the Society, as well as Art-Workmen, are invited to inspect them daily between the hours of 10 and 4.

To suit the convenience of Artizans, the Exhibition will be open on the evenings of Wednesday, Thursday, and Friday next, from 7 o'clock to 10.

The Council have invited a Special Meeting of the Exhibitors and Friends for Monday evening next, at 8 o'clock.

Proceedings of Institutions.

BINGLEY MECHANICS' INSTITUTE.—The completion of the new Mechanics' Institute at Bingley was inaugurated by a soîrée on the 14th of November. The Institute is built from the designs of Mr. Waterhouse, of Manchester. The style of architecture is Gothic, and the building forms a prominent and attractive object in the main street. The Institute consists of a large school-room for the accommodation of the evening classes; four class rooms, for the teaching of the more advanced branches of education; a library, news-room, and a large hall for the delivery of lectures. The hall is capable of accommodating upwards of 500 persons. **ALFRED HARRIS, jun., Esq.,** the President, occupied the chair, and amongst a large number of gentlemen who supported him were **E. Baines, Esq.,**

M.P., W. E. Forster, Esq., M.P., Alfred Harris, Esq., Isaac Holden, Esq., Mr. Alderman Law, Rev. A. P. Irwine, M.A., Samuel Rhind, Esq., Thomas Baines, Esq., Rev. A. McKechnie, Capt. Ellis, Bingley; H. Illingworth, Esq., Bradford; J. Oddy, Esq., Birkenshaw; T. Horn, Esq., Morton; E. Sharp, Esq., A. Sharp, Esq., J. N. Thacker, Esq., Mr. W. E. Skirrow, Mr. B. B. Skirrow, Mr. J. Dickenson, &c.—The CHAIRMAN said—The inauguration of this new building is an event which has been for several months looked forward to with great interest by most of the inhabitants of our town; and in now meeting to celebrate it, we may safely say that the anticipations which have been formed of the general appearance of the building—of its convenience of arrangement, and general adaptability to the purposes for which it is intended—are fully realised. It will, I am sure, be evident to all who are here this evening, that this building is one which is likely to give scope for a great spread of educational influence in our town. It will be surmised that the result we have attained could only be arrived at by a considerable outlay of money. The cost of the building and furniture, including the various items for heating, lighting, and decorating, will not fall short of £2,600 when all is completed, and the subscription list, standing still at £1,410, causes us some little anxiety as to the pressure of the heavy balance of debt on the Institution. A Mechanics' Institute was first founded in Bingley by a few friends of education in 1832. After a languishing existence of five years it came to an untimely end, but was renewed in the year 1840. It continued on a small scale, with more or less success, until 1849: in that year the rooms were taken in which it has been carried on up to the present time. At the annual meeting in 1863, the number of members was 341; this year it is 411. The increase has been principally in female members: last year these numbered only 26, this year there are 63. In the library there are 1,196 volumes of books. The books have been much better read in the current year than in the year preceding, the issues being 5,008 in 1863, against 6,112 in the current year. These numbers show that the members have made a diligent use of the small library which we possess. During the past year lectures have been delivered by the Rev. P. A. Irwine on "Mahomet," Rev. J. Ward on "Earthquakes," Rev. Mr. Heron on "Young Bingley," Mr. W. Newsome

on "Self-Culture," and Mr. N. Waibank on "Crusades." A penny bank, in connection with the Institute, has been several years in operation. The influence which literature exercises over the minds of young people, especially those who seek it of their own accord, either for instruction or for amusement, is so great that Mechanics' Institutes should furnish to their members the very best class of reading, and works in each department of literature should be carefully and judiciously selected for the library. I am by no means an advocate for placing in the hands of our members dry and abstruse treatises or works of a nature too learned for the general abilities of the readers for whom we have to provide; but there are now many works published which it is desirable for these Institutions not to encourage—works which are not wholesome intellectual food, and the reading of which neither enlightens the mind nor elevates its moral susceptibilities, works which do not give a true picture of human life, but which appeal to the lower feelings of man's nature, by gross exaggerations of the vices and follies of the vicious and foolish of our species. The influence of works of fiction on the mind is by no means to be under-estimated as an element in mental culture, especially for the hard-strained sons of toil who seek, and justly so, in their literary pursuits, relaxation from the hard stress of labour; therefore, in selecting works of this class from the large field now laid open to the reading public, we should exercise much discretion, so that we may place before our members a good and wholesome intellectual diet, scrupulously avoiding all that is of a baneful or poisonous nature. It may perhaps surprise some of our friends from a distance to hear that the young lads of Bingley, to the number of 100 and upwards, are regular attenders at the night school, and may be seen zealously plodding over their slates and copy books of an evening, instead of wasting their time in idleness or vice. The girls' school, too, is in a flourishing condition, and is attended by about 50 of the female members of our Institute. Whilst these facts are very encouraging, we feel that a wider task is opened before us, and that we must try to lead on our young members who attend the evening schools into higher knowledge and more noble attainments. French and German are now becoming necessities of commercial as well as of intellectual life—they should be freely encouraged here for those who desire to learn and who will afford the necessary time and cost to attain them. The study of history, a most important branch of education for the working classes, should also find its votaries within these walls—and a well-regulated course of historical study requires the mechanism of master and pupils to make it efficient. Mathematics and mechanics, too, are highly important to our working men in this district, where each man earns his bread by directing and assisting those great forces, steam and iron, which, brought under the control of human intellect, have been moulded and framed into machinery whose magic power is only equalled by its fairy fineness. The number of members attending the drawing-class is but small, yet if our working men and women knew that one of the greatest requirements of our age is experienced art-labourers, they would consider rather seriously whether within themselves may not lie concealed the germs of that glorious faculty which enables mankind to create worlds of beauty, of grace, and of comeliness, out of materials low and base in themselves. I repeat that one great want of our age, in architecture, in pottery, in manufactures of every kind, is an array of art-workmen and art-workwomen; and I assert that more agreeable, more noble, and more profitable employments, available for the poorer classes of our population, do not exist than those of skilled art-workmen and designers. But in these departments spurious knowledge is worse than worthless, it is positively baneful—therefore the necessity of earnest study in their attainment. I know great difficulties have to be overcome in the study of art (as in all other noble studies), and one of these is the temptation to the young

student to become an artist. If any young men are here who are studying at the drawing class, my advice to you is, learn what is useful, not what is fine; learn what you can apply to your trade, what will help you in earning your daily bread. Don't strive to paint pictures except for your own amusement and pleasure. You may learn to succeed in drawing models for machinery, in applying your knowledge to stone-cutting and wood-carving, or you may learn to design a pleasing combination of colours, or a simple pattern for a dress-piece; but do not be led away by the idea that you will paint pictures which will sell, because you will, as a rule, only experience disappointment if you are. The name Mechanics' Institute hardly conveys a proper notion of the actual composition of a society like ours. The members in this Institution belong to all classes of society, from the gentry of the neighbourhood to the master manufacturers down through the various grades of tradesmen and shopkeepers, shopmen, overlookers, clerks, farm labourers, combers, weavers, and spinners; resting thus on the broadest possible basis, it stands safe against the accusation of being subject to any class or party interest; and it is of the utmost importance that this broad basis should be carefully preserved; and also that every adult member should feel a personal interest in seeing that the management is confided to those in whom entire trust can be reposed, and who will work the Institution for the general good of the whole body of members, without party or sectarian leanings. In the early days of Mechanics' Institutes, it was considered by some, who had the welfare of the people at heart, that it was desirable not only that they should be principally composed of, but that they should be entirely conducted by, working men. At first sight there may be reasons which commend this view of the subject, but I never could agree with the propounders of the theory; for I am strongly of opinion that one great benefit resulting from Institutions of this kind is the friendly intercourse which they promote among the various classes of the community, and the creation of kindred interests and feeling between them by the kindly co-operation of rich and poor, of high and low, in one common object—the alleviation of moral want, and the supply of mental food to those whose position in life may prevent them from obtaining it elsewhere. I believe that these good feelings and sympathies between class and class do grow out of these Institutions when conducted on sound principles—that good results are produced to all who impart or receive their advantages—and that all who attempt to narrow the basis on which their moral structure should rest, by centralising the control of them in any one class, are not the true friends of the working people. Our own Institution is a fair sample of the results of united efforts among the various classes of our townspeople. Had it not been for the active help and liberal donations of the middle and upper classes, it would have been impossible for this Institution to have possessed the handsome building in which we are now assembled, and which may be regarded as an inheritance committed to trustees by the friends of education and mental enlightenment for the benefit of all classes of the inhabitants of this town, but, of course, especially for the benefit of that large, hard-working, and industrious class of artisans, who could not have obtained such an advantage for themselves, except by sacrifices which it would have been hard for them to make, and unreasonable to have been expected from them; no further stipulation being required from those who enjoy it, but a steady adherence to the principles on which this Institution is founded. And again, had it not been for the hearty support which the Institute, on its old basis, received from the working population, there would not have been a sufficient inducement for the middle and upper classes to come forward, as they have done, to supply the want of increased accommodation so keenly felt by the members. Here, then, we see an example of what may be done by the kindly co-operation of class with class. And it may be felt as a cause of

thankfulness by some that they may impart, and by others that they may receive, the benefits which the Giver of every good and perfect gift places it in the power of one man to give and another man to enjoy.—Mr. E. BAINES, M.P., referring to the many branches of education in science and art which might be embraced in the curriculum of the Institute, urged the importance of the members taking part in the examinations instituted by the Universities of Oxford and Cambridge, and illustrated the value which was attached to one of their certificates by relating the case of a young man—an old member of the Leeds Mechanics' Institute—who obtained an excellent situation in the back States of America by producing as his reference such a certificate. It was not merely a certificate of a certain amount of requirements on the part of the man; it was a certificate of habits of application that had been learned in the Institution and of the good effect produced on his moral character by his connection with the Institution. He then alluded to the superior advantages enjoyed by the young men of the present day over those enjoyed when he was a young man, and referred to the increase which had taken place in cheap, good, and abundant literature to an extent which not even the most sanguine could have dreamt of thirty years ago. From the year 1831 to 1864, the issue of newspapers in the United Kingdom had increased more than thirteen-fold, and that of serial publications more than fifteen-fold. As regards the quality of these publications, he might mention that of the 3,600,000 copies of serials issued monthly in London, 1,900,000 were positively religious magazines; one quarter of them were issued by the advocates of temperance and total abstinence, and the rest were magazines of a high literary and scientific character. The circulation of the weekly publications was 2,500,000, and of these one-fifth were distinctly religious; one-third were of an educational and literary order; two-fifths were novels, tales, and biographies of an unexceptionable character, and only one-twelfth were of that directly immoral and impure character to which he supposed the Archbishop of York referred, when, in a recent speech, he condemned sensational novels, and those romances which were calculated to excite wonder and horror—such miserable trash that he wished there were none of them. Only 9,000 copies out of 2,500,000 published weekly had an immoral tendency, and he found that three years ago the number was 52,000. Those issued of a sceptical or decidedly irreligious character only numbered 5,000. With the advantages conferred by Institutes like the present, and by such a large mass of valuable, pure, sacred, moralising, elevating literature, the young men of the present age ought to be a more enlightened, more active body than their fathers could by any possibility be. He hoped that to the hard heads and good principles of their fathers the young men of Bingley would add that knowledge which would make them more useful to themselves and to the world around. After alluding to the recent working men's industrial exhibition in London, as proving that the working men of England could turn their talents to other trades besides their own, and that a change of occupation was more of a relief and amusement to working men than time spent in frivolous amusements, Mr. Baines concluded by recommending the Committee of the Institute to issue a circular yearly to the youths who were retiring from school, inviting them to become members, and also take an active interest and sympathy in their studies.—Mr. W. E. FOSTER, M.P., congratulated the assembly upon the inauguration of their Mechanics' Institute. They had certainly got the most handsome building of the kind he had ever seen. When Mechanics' Institutes were first started, under Dr. Birkbeck, they were a little too ambitious, and thought it would be possible to dispense altogether with elementary teaching and to give the working man a superior education. It was found, however, that artisans did not possess that elementary education which would enable them to take advantages of the higher branches of learning, and the result was that these Insti-

tutions fell away from their original design, and they became Institutions more for the education of the middle class than the instruction of the mechanic. These Institutions had found that they could not impart a superior education to the working man until he became master of elementary learning. Consequently, elementary night schools were acknowledged to be one of the principal objects of Mechanics' Institutes, and he did not think that there was anything that did so much good. He hoped that no person would feel discouraged in acquiring elementary learning, because he had not had the advantages of early learning. He had had at his house, when on a visit to this neighbourhood, a very gentlemanly man, who did not learn to read till he was twenty-one or twenty-two years of age, and yet he was now a very able and intelligent man. He believed that it was only this year that this same man, at the meeting of the Association for the Promotion of Science, at Newcastle, made a speech in defence of a particular theory, and which was acknowledged to be by far the best speech on the occasion, even in a discussion amongst scientific men on a scientific question. This man was William Craft, the Negro, and formerly a slave. They need only take the example of William Craft as an illustration of what a man might effect for his improvement when he had a determined purpose. He was glad to find that there was a class for the study of the French language connected with the Institute. A knowledge of the French language was becoming of more importance every day. Now that there was a large trade between this country and France, it was necessary that all those who were employed in this trade should have associated with them those who were competent to speak and write the French language. A knowledge of the French language, therefore, would be of the greatest advantage to young men in enabling them to obtain better situations and to promote their own advancement. It was the duty of all to promote the education of the people to the fullest extent. Whatever progress was made in England, he believed that the West Riding would be in the van. It was more necessary that in this district the working classes should be prepared to assert their position in the van of England's progress. What they were doing at Bingley was a proof that they understood the position they were destined to occupy.

LLANELLY ATHENÆUM.—On Friday last, 23rd December, Mr. F. E. Bodkin concluded a course of four lectures on Geology, which he has delivered at this institution. Mr. Bodkin has kindly taken the trouble of classifying and arranging a large collection of minerals presented to the institution by Lord Cawdor, and had at the earnest request of the managers consented to deliver the lectures in question, which have been extremely well received; a cordial vote of thanks having been tendered to the lecturer at the termination of his voluntary and gratuitous labours. Mr. F. Bodkin is the grandson of the Assistant-Judge, one of the Vice-Presidents of the Society of Arts.

ST. GEORGE'S AND ST. JAMES'S, WESTMINSTER.—On Friday, 23rd December, a public meeting of the St. George's and St. James's local board for promoting the education of adults, in connection with the Metropolitan Adult Educational Association and the Society of Arts, was held in the lecture theatre of the School of Mines, Jernyn-street, to explain the objects of the board, the system of examinations, certificates, prizes, &c.; Wm. Hawes, Esq., in the chair. The Chairman said the objects of the association were very important. In former times young men had no means of testing their abilities or acquirements; but when the Society of Arts established the system of examinations, conducted by the agency of local boards, every man could offer himself for examination. The chairman proceeded to detail the objects of the association, and urged the young men and women employed in the district in shops and other avocations, to join the association with a view to future improvement and success.—Dr. Drewitt proposed the first resolution—

"That it is desirable to promote as far as possible the education of adults; that the present time, owing to the early closing movement, furnishes a fitting opportunity for carrying out the object, and that this meeting pledges itself to use its best efforts for the purpose;" this was seconded by the Rev. Mr. White, and unanimously adopted. The Rev. Mr. Macilwaine, in moving a resolution acknowledging the steps which had been taken by the Society of Arts and the Metropolitan Association for the Promotion of Adult Education, expressed an opinion in favour of local organization as the best means of rendering those steps more effective. The motion was seconded by the Rev. Mr. Edwards and unanimously agreed to. A resolution to the effect that the union of interests between the inhabitants of the parishes now appealed to afforded special facilities for the formation of a united local board in connection with the present association and the Society of Arts, was also unanimously agreed to; and the meeting then separated with votes of thanks to the Duke of Marlborough for accepting the office of president of the local association, to the committee of Privy Council on Education for the use of the theatre, and to the chairman for his conduct in the chair.

DUBLIN INTERNATIONAL EXHIBITION, 1865.

The Belgian Commission (at whose head is placed M. Fortamps, the able Commissioner in 1862) have forwarded the list of their own manufacturers who purpose to become exhibitors. Lace, of course, occupies a prominent position, and we are able to report that Belgium will be remarkably well represented in this important branch of industry. The well-known firm of Cail, Halot, and Co., have promised railway and agricultural machinery and engine-tools. Chemical manufactures will include ultramarine, soaps, and perfumery. Liège will send a large display of arms, especially rifles; and Ghent a collection of leather goods. Metallic manufactures, glass, and china, are all to be well represented; it is only necessary to mention the name of Dufour among the goldsmiths, Demol for porcelain, and Bogaerts for bronzes. The names of contributors to the Fine Art section are too numerous to quote; but we are assured that the best specimens of the modern Belgian school of painting will have a place in the Exhibition. Among the painters, Billoin, Kindermans, Keelhoff, Roffaen, Van Moer, Van Severdonck, Verboekhoven, and Willems, are already known by their works in the Great Exhibition of 1862. Among the sculptors and metallists, we may, for a similar reason, specify Fraikin, the two Geefs, and Wiener.

INVULNERABLE AND UNSINKABLE SHIPS OF WAR.

By J. KENNEDY.

If in theory the science of attack has no limit, neither has the science of defence; the latter will develop with the former. A big and powerful gun means a big and powerful ship; and if ships are to be armed with 300 and 400 pounders, the defensive armour on the exposed parts of the ship's hull must be made to resist this gun, for it will not do to let the projectile get inside of the ship or pass right through, as it might enter just above the water-line and pass out on the opposite side below the water-line, and so bring about the destruction of the ship. A ship may be shielded to effect this object, though her dimensions must be augmented, not by adding to the length, but by increasing the beam considerably. The height of the solid work (a top height) above the water-line being exposed surface, and having to be covered with armour, is a fixed particular; for, whatever the other dimensions may be, she must—for a comfortable ship when cruising at sea duing bad weather—have a certain height of top side out of the water, or else the upper deck

will be constantly swept by green seas. This height may be limited to ten feet above the loaded water-line, when ready for sea, in the case of all iron-clads, though it precludes the use of broadside guns as carried by the *Warrior* and her sister ship. This surface above the water line tumbles home very considerably, and is convex throughout, fore and aft. The proposed descriptive dimensions of this ship are:—For length on the loaded water-line, 400 feet; breadth outside, 82 feet, and depth in the water as she would be ready equipped for sea, 22 feet; tonnage, builder's measurement, 12,546 tons; loaded displacement to 22 feet depth, 13,500 tons, with a formation of immersed surface which at all points will offer the finest angle of contact to the water particles during a direct motion; with due inherent stability for resisting the momenta of all the weights carried aloft, viz., defensive armour, turrets, and guns, &c., when oscillating heavily in a rolling sea-way, and thus avoid the necessity for carrying counter-weighting; without any vertical surface at the extremities, as gripe and heel, or dead wood, which opposes the lateral motion of the bow and stern of the ship during steerage, and gives the rudder more work to do: and with a double or bifurcation of the ends fully developed at the after body and partially at the bow body; an easy bilge section outside the midship longitudinal body, which is 30 feet wide; parabolic, horizontal, and diagonal sections, and elliptical cross-sections of the outside longitudinal bodies, and fitted with two propellers and two rudders upon the double after ends, the propeller shafts being hinged at some distance from the propellers, to allow the propellers and shafts to be hauled up together into suitable recesses in the counter, a ready way of disposing of them when canvas has to be the only propelling power.

The outer shell of the hull may be precisely the same as any ordinary iron ship, being virtually one unbroken skin up to the top-height. The armour, which is carried inside of this shell upon shelves of sheet iron 12 inches apart, consists of slabs of rolled or hammered iron of any convenient length, with a triangular or wedge-shaped section six inches deep at the thick edge, and twelve inches broad. These are piled flat way on the shelves, one above another, thick and thin edge alternately having layers of felt placed between each. The whole depth of the armour is then substantially backed up by stout iron framing and truss work from the inside, which is continued down to the flat floor. Strong diagonal braces of iron connect the upper portion of the ship at one side with the bilge on the other. These are any convenient distance asunder, and need not interfere with a free course throughout the ship between decks. They will impart great stability to the armoured portion of the ship's hull, and prevent any vibration taking place.

After the necessary space has been set apart for the engines and boilers, coal bunkers, powder magazine, and for the stores and equipment, the remainder of the space in the hull below is divided off into numerous well spaces, which are to be ten feet square, and from the lower deck down to the flat floor. These well spaces are made by dividing this portion of the ship off by means of vertical partitions or bulkheads, fore and aft and athwart. These partitions are to be of thin iron or steel, and a few of them will be continued up to the upper deck. They will thus impart great strength and rigidity to the structure, as well as render the ship less liable to be sunk. The upper deck beam plates are covered above and below by thin iron sheeting, to enclose a water-tight space partitioned off, which corresponds to the depth of the beam plate. Some hundreds of tons of floating power can thus be gained. The lower deck consists of iron sheeting carried over the upper edges of the transverse and longitudinal bulkheads. No beams are required at this deck. Man-holes or doors are made over each well space. A double skin throughout the bottom, giving a space of some 24 inches, would be a further advantage, by way of diminishing the chances of sinking. By way of a further

precaution against the liability of these iron ships to sink without giving any warning, all the spare room below the 'tween decks is occupied by thousands of light, hollow, spherical vessels. These are made of steel, or malleable iron of very tough quality. The figure of the sphere or globe, being that capable of offering the greatest resistance to external pressure, is preferred. They may be 24, 36, and 48 inches in diameter. A sphere 48 inches in diameter contains 31·51 cubic feet in the solid, and 500 of them would be equal to 16,755 cubic feet, which, reduced to tons of water, equals 478½ tons, and if we allow five tons for the weight of metal in them, they yield 473½ tons of floating power. This shows that were these hollow spherical vessels placed in the compartments, not otherwise occupied, in sufficient numbers, they would guarantee the ship from being sunk under the most destructive fire from forts or ships. The chances would be very much in favour of a ship so provided with this description of floating power holding out to the last. In preparing a ship to go into action all the available space, even between decks and in the engine-room and about the boilers, might be filled up with these spherical hollow floating vessels, for all that can be done in this respect, no doubt, would be only a prudent precaution against instant destruction by sinking.

As regards the means of obtaining sufficient numbers of these hollow globes, they may be manufactured by existing machinery, and turned out in considerable numbers by a few men and boys in a very short time; and, as one essential property they must possess is extreme lightness, the quantity of metal used up in their manufacture will be very small, and the cost, therefore, will be comparatively trifling compared with their immense utility.

The problem of how to apply iron, steel, or any other suitable metal of excellent quality, to the construction of ships of war or other vessels, so that the greatest amount of strength with lightness may be gained, and at the same time to render the structure incapable of being sunk until it is absolutely broken up, is a very simple one, and may at once be practically resolved, whilst the question of invulnerability to attack by 400 pounder guns depends upon providing a ship of sufficient buoyancy, with great proportionate beam, and in doing away with the present broadside armament as carried by ships of the *Warrior* class.

A ship of the above description, in lieu of broadside guns, would have two rows of fixed turrets carried on the sides of the upper deck, close up to the waterway, and a turret at each extremity of this deck—ten turrets in all—armed with two guns in each, of the heaviest calibre, with sheet-iron bulwarks arranged between the turrets, adapted for sliding down inboard.

Fine Arts.

DESCRIPTIVE LABELS IN THE LOUVRE.—An excellent method of furnishing the public with information respecting works of art is now being put into practice in the gallery of the Louvre. Tablets, on which are inscribed the subject of the adjacent pictures, together with the names of the artists, the dates of their births and deaths, and the title of the school to which they belong, have been placed, at intervals of about six yards, along a portion of the Italian department of the gallery. These tablets are conspicuous enough to attract attention, and cannot fail to make many persons, unversed in matters of art, think a little, at least, about the pictures, which otherwise they might, and very often do, regard as mere pretty curiosities, and this will be a real step towards art education.

SALES OF WORKS OF ART IN PARIS.—The true fine art season in Paris will commence with one of the most important sales that has taken place for a long period, the famous collection of the late Comte de Pourtales-Gorgier, who died ten years since, known as the Pourtales gallery.

The sale is divided into ten portions, to occupy thirty days, and is spread over the period commencing with the sixth of February, and ending on the fourth of April. The catalogue is divided into three portions—objects of art and curiosity, medals, and pictures. The various sections will be sold in the following order:—Egyptian and other ancient bronzes, terra cotta, &c.; painted Greek vases—these alone will occupy four days; engraved gems and stones, statuettes in silver, jewels, and ancient glass; medals, ancient and modern; sculpture in marble, ivory, and wood; bronzes, faïences, enamels, arms, &c., of the middle ages, and renaissances; ancient curiosities of various kinds, European and oriental; ancient sculpture, tables, vases, &c.; modern paintings; and lastly, the works of the old masters, drawings, &c. Amateurs, and all connected with the fine arts, are looking forward to the Pourtales sale with great interest.

MISCELLANEOUS SALES.—Pictures and other works of art are fetching small amounts at the present moment in Paris. At a sale, consisting principally of works from the Chateau de Belfort, a holy family, attributed to Andrea del Sarte, the Virgin, with the infant Jesus on her knees, Saint Elizabeth, holding the young Saint John by the hand, opposite, and Joseph behind the Virgin, was withdrawn at 10,000 francs. "The Three Graces," and "Mademoiselle de la Vallière," by Pierre Mignard, formerly the property of Louis Philippe, a large picture, was purchased for the Troyes gallery for £100; a portrait, by Govaert Fluck, sold for £40; "Le Passage du bac," by Salomon Ruysdael, 960 francs (£38 8s.); "Pilgrims praying before a Chapel," by the elder Teniers, only fetched 245 francs (£9 16s.); and a group of peasants dancing before a farm, by the same, 411 francs (£16 8s. 10d.). The well-known "Girl with Dog," supposed to be by J. B. Grenze, fetched 354 francs (£14 3s. 4d.); a landscape, with animals, attributed to Cuyp, was withdrawn at 10,000 francs; a head of Cæsar, by Ary Scheffer, sold for only 150 francs (£6).

CHURCH DECORATION IN PARIS.—A sum equal to £11,584 has been devoted to the decorations of the new Church of St. Augustin. The interior of the cupola is to be illuminated with large figures, sixteen in number, of prophets, saints, and fathers of the church, surrounded by cherubim, on a blue ground, studded with golden stars; in the pendentives are to be painted the four evangelists, accompanied by angels; the vaultings of the side chapels are to be painted with six subjects from the lives of St. John, St. Peter, and St. Paul; these, with one or two minor commissions, amount to nearly £2,880. The stained glass, and three medallions beneath the porch, in distemper colours, enamelled, amount to £2,760. The sculpture includes a bas-relief, for the porch, of Christ and the twelve apostles; a marble statue of the Virgin Mary; more than twenty statues of the evangelists and saints, for the decoration of the façade of the building, with minor works in stone, and bronze figures for the doors—together, £5,944.

MONUMENT TO COUNTS EGMONT AND HORNE.—On the seventy-fourth anniversary of the birth of King Leopold, a fine monument, by Fraikin, in memory of these victims of the ferocity of the Duke d'Albe, was uncovered in the Place of the Hotel de Ville, at Brussels, where they were beheaded in 1568. The Burgomaster had specially invited the attendance of the presidents and members of the societies of archers and crossbow-men, who still keep up the customs and oaths of the ancient guilds. These companies, in 1568, in spite of the despot who then ruled over the land, took upon themselves the honour of paying the last tribute of respect to the remains of the unhappy counts. It was right that their representatives should in 1864 have the honours of the inauguration of the expiatory monument. The pedestal has, with more than doubtful taste, been adapted to the purposes of a public fountain. It is true that the French have done the same in the case of Molière and others, and that we have, once at least, committed the like solecism, but a hundred such

precedents would not warrant such a violation of good taste and propriety.

PUBLIC STATUES AND PORTRAIT GALLERIES.—The *Conseil-Général* of the Meuse has decided on creating, in the town of Bar-le-Duc, a gallery of portraits of the generals and marshals natives of the department, and the execution of the portraits has been confided to M. Gabriel Lefebvre, a painter of history. It is hoped that other departments will follow so good an example, but that the list will be extended so as to include not only the military, but also literary, artistic, scientific, and other celebrities. Everybody can understand a portrait, and local *amour propre* alone would render such galleries popular, and aid the growth of a taste for art. A statue is to be erected at Villers-Bocage, near Caen, to the great self-made manufacturer Richard Lenoir, after whom one of the new Paris boulevards is named; the work is entrusted to M. Louis Rochet, the sculptor of the equestrian statue of William the Conqueror, so popular in Normandy, and it is to be finished next year, and inaugurated on Lenoir's centenary anniversary. The funds have been supplied by subscription amongst the inhabitants of the department of Calvados. The Minister of the Fine Arts has just presented the town of Abbeville with a magnificent marble bust of the poet Milleroy, who was a native of that place. The competition for the statue of M. Billault to be erected at Nantes, has failed, none of the designs having been considered satisfactory. Four of the competing artists have been invited to send in other models. It is whispered that the sum devoted to the purpose of the statue is so small that artists of known ability and standing declined to enter the list.

ARTISTIC BENEVOLENCE.—A young painter of Paris having been struck with paralysis, a number of his brethren resolved to contribute each a picture or drawing to be sold for his benefit. The sale took place the other day, and realised 15,000 francs (£600). Four pictures, by M. Corot, fetched 2,080 francs; one by Daubigny, 875 francs; a Bonnat 340 francs, &c. Such an act of benevolence deserves to be recorded.

SALE OF OBJECTS OF VERTU.—The collection of a well-known artist and amateur, the late M. Mathieu Meunier, was sold in Paris last week, and exhibited the growing taste for old *faïence* and other productions of that class. A large rustic basin, by Bernard Palissy, sold for 600 francs; a curious circular dish, or salver of Pesaro ware, of the sixteenth century, bearing the inscription, "*Io ma Rechon an da Dio*," and decorated with a figure of a knight in armour, after the style of Albert Durer, 280 francs; two apothecaries' beakers, of Florence ware, 200 francs; a plate of Persian manufacture, 301 francs; a large vase, ornamented with flowers in relief, made at Marans, near La Rochelle, 470 francs; a large apothecary's beaker (*aignière*), of Nevers ware, 335 francs; a number of plates, jugs, basins, and other articles of Rouen manufacture, from 100 to 200 francs each; a small finger fountain, of the ware of the south of France, decorated with a view of Marseilles, 310 francs; a large covered cup, of the same kind of manufacture, 310 francs; an oval dish, of Moustiers make, 260 francs; a Burmese knife, the blade damascened, 860 francs; a carved boxwood comb, inlaid with ivory in colours, an Italian work of the fourteenth century, from the Debruges, 305 francs; an engraved key, French, of the sixteenth century, 325 francs; a Gothic lock, 420 francs; two large cups, in Venetian glass, ribbed blue and gold, 450 and 430 francs respectively. In the same sale, a marble statue of the Queen Marie Amelie, by M. Meunier, after a small model by Pradier, sold for 2,100 francs (£84).

CONVENTION BETWEEN FRANCE AND SWITZERLAND, RESPECTING WORKS OF ART, &c.—A convention has been signed by the two governments, by which the literary and artistic productions of each country will be protected in the other. The convention is for twelve years from the 1st of January, 1866, and applies to printed matter, music, and works of art of all kinds.

Manufactures.

CHINA GRASS.—A very important paper has just appeared in the *Moniteur* of Paris, namely, a report approved by the Chamber of Commerce of Rouen, on the value of "China Grass as a Rival of Cotton." Previous announcements had appeared, in which great expectations were held out, and now we have the recorded opinion of experienced men, backed by the approval of the Chamber in the same sense. Passing over the enthusiastic expressions with which the report is introduced, we proceed to extract the mere facts as given in the report in question. In the first place the samples and products, on which the report is based, were exhibited for several weeks in the hall of the Chamber of Commerce at Rouen, and inspected by a large number of manufacturers of and beyond the district of which that town is the centre, a fact which the reporters quote as giving additional weight to their conclusions. "We made it our duty," says the report, "to collect the observations which reached us, and all may be summed up in this—that the specimens exhibited show excellent results corresponding exactly with the propositions of the Chamber, namely, to find a fibre capable of being manipulated without difficulty by means of the machinery used for spinning and weaving cotton, and which, moreover, can be dyed by the same processes as cotton; in short, everything tends to prove that a true substitute for cotton has been found." The first experiments having been made with small quantities of the grass, the Chamber purchased about six cwt., a third of which was operated on by the reporters or under their inspection, with the following results:—The grass was mixed with an equal quantity of Indian cotton, and worked in the ordinary manner; the carding alone presented some difficulties, but these the reporters believe may be very easily removed. No difficulty arose in the spinning. The yarns produced were Nos. 11 and 17, and these were employed in making a piece of *Cretonne*, military calico, 76 centimètres wide, and weighing 17 kilogrammes per 100 mètres, and four pieces of *Longotte*, or coarse cotton for printing, each measuring about 85 mètres, 93 centimètres in width, and weighing 16½ kilogs. the 100 mètres. The mixture of China grass is said to give to the fabrics increased strength. The mixed yarn was rather less elastic than one of pure cotton, but this rigidity is regarded as an advantage as respects the duration of the fabric produced. As regards dyeing, eight cuttings of the mixed fabric were treated together with a similar number of pieces of pure cotton by the madder process, and the black, red, purple, violet, and orange are declared to be all that could be desired. Some doubt was felt about the "violet savonné," but the result is reported to be equal to that of the same colour obtained with pure Louisiana cotton, and even more brilliant. The deduction is that China grass has as much affinity for colours as the best cotton, that mixed with inferior cotton a "good middling" is obtained which dyes as well as the best average cottons, and that, consequently, there is a real economy in the employment of China-grass as regards taking colours. As respects elasticity and resistance the *Longottes* in the rough was 93 centimètres wide, and when bleached and dyed 80; 157 $\frac{1}{2}$ mètres of the former gave 161 $\frac{1}{2}$ of the latter, a result, equal it is said, to that of fabrics of Louisiana or Jumel cotton. The weight, too, bore the same proportions, namely, about one-eleventh less after bleaching and dyeing. Strips of the mixed cloth, ten centimètres long by five wide, were tried, for strength, by the dynamometric test, adopted by the Minister of War, and the result, as compared with similar strips of cotton unmixed, was as follows:—suspended the way of the warp, the mixed fabric exhibited rather less, while by the warp it had the advantage. As to the important element of price, the following are the facts set forth:—100lbs. of China grass yield 75 parts of yarn, 8 parts fit for paper-

making, and 17 parts waste, fit for manure. The cost of the fibre, as prepared for spinning, is put at 1fr. 57c. the kilogramme, or less than 7d. per lb., presenting an economy, as compared with Egyptian cotton at the present time, of nearly two shillings a pound! Such are the deductions to be drawn from the report in question. In addition to this, it must be added that the China grass will, it is said, grow with as little trouble in the south, centre, and west of France, as it does in Algeria, the West Indies, Senegal, India, and Guiana.

COAL IN FRANCE.—In excavating for the Bourbonnais Railway, says the *Progrès de Lyon*, at a distance of two or three hundred yards above L'Arbresle, a small town about fifteen miles from Lyons, a seam of coal, which is said to be good, has been laid open. This accidental discovery is considered highly important, as indicating a coal deposit in this neighbourhood at no great distance from the soil. France is not wanting in coal, but it exists in many cases where no economical means of transport are yet established. No doubt good coal in the neighbourhood of such an important manufacturing place as Lyons would be a great boon, but all the world knows how deceptive are such discoveries as the one referred to; and we have not a geological map of France at hand to tell us whether there is anything new in the existence of coal in that quarter. Such facts, however, deserve to be noted, now that the import of English coal into France has grown so enormously.

NEW THERMOGRAPH.—M. Marey, of Paris, has invented a new registering thermometer. It is an adaptation of the air thermometer, and consists in a metal bulb attached to a tube of the same, which is but a fifth of a millimetre, or 0.0079 inches, in interior diameter; the receiver or indicator of temperature is a glass tube, bent into the form of a half-circle, one extremity being closed and attached to the circumference of a metallic wheel, resting on knife edges, and counterpoised. A mercurial index is introduced into the glass tube, which it divides into two chambers, one closed and the other open; and the metallic tube of the thermometer is passed through the mercury, into the closed chamber of the glass tube. On the axis of the wheel above mentioned is an arm, carrying a tracing point, which marks the variations on a registering cylinder. When the bulb is heated the air passes into the closed portion of the glass tube, forces back the mercury, and of course disturbs the equilibrium of the apparatus to an extent marked by the tracing point on the cylinder. The metal air tube is furnished with a valve near the bulb, so that the interior may be placed in communication with the outer air, in order to set the apparatus at zero. This is one of the instruments furnished to the scientific expedition for Mexico.

SUN MOROCCO.—The other day a means of cooking by the aid of the sun, was proposed by M. Babinet, of the French Institute; another professor, M. Mouchot, suggests an application of the sun as a motive power. If, he says, a bell or cylindrical reservoir, of thin silver, blackened within, be filled half with water and half with air, and let the sun's rays fall upon it through two bell glasses placed over it, the air will expand and press upon the water. If a tube with a stop-cock be inserted near the lower part of the silver reservoir and curved upwards into a vertical position, the water upon the opening of the cock will leap to the height of ten metres, and the fountain will be maintained as long as there is any water in the receiver, but the moment any body intervenes between the sun and the receiver, of course the action diminishes, and soon ceases entirely. M. Babinet thinks that such an application of the sun's power might be of advantage in Egypt, where, as he says, "the sun costs nothing."

SCOTCH PIG IRON.—The export of Scotch pig iron in the first ten months of 1864 amounted to 551,929 tons, against 539,490 tons in the corresponding period of 1863, 497,676 tons in the corresponding period of 1862, 497,706 tons in the corresponding period of 1861, and 466,325 tons in

the corresponding period of 1860. Notwithstanding some depression in the exports in September and October, this year's exports show, as compared with 1863, an advance of 14,499 tons; as compared with 1862 an advance of 64,253 tons; as compared with 1861 an advance of 64,223 tons; and as compared with 1860 an advance of 85,604 tons.

SLATE IN NEW SOUTH WALES.—Some pieces of slate have been brought down to Sydney, from a quarry on the property of the Ophir Mining Company, about twenty-five miles beyond Bathurst. The samples have been pronounced by competent judges of the material to be of a very good quality, and to be well adapted for flagging, making cisterns, and various other purposes. It is also stated that the edge of the slate would cut in two-thirds of the time that the Welsh slate takes to cut, by hand process, while with the chisel it cuts free and is not likely to flake up. The slate exists in great quantity at Ophir, and the discovery promises to be of considerable importance.

PRESERVED FISH.—Messrs. Marshall and Co. have commenced a fishery and curing establishment at Lake Macquarie, New South Wales, where they are preparing to go extensively into the business of supplying the citizens and the colonists of the interior with fresh fish, in hermetically sealed tins, after the manner of those sent out from England. At present, the number of men employed can turn out half a ton per diem of 1-lb. and 2-lb. tins of fish. The fish—caught in the lake, or immediately outside its entrance from the sea—consist of whiting, flat-head, bream, snapper, salmon-trout, mullet, and guardfish, forming as good an assortment as can possibly be desired.

SILK CULTURE IN AUSTRALIA.—Mr. F. G. Croft, of Penrith, has purchased about 20 acres of land, near his residence there, to be applied to the cultivation of silk. He has also purchased the whole of the fine lot of mulberry trees (*Morus multicaulis*), belonging to Mr. John Muston, at the North Shore, specimens of the leaves of which excited such favourable attention at a late meeting of the Acclimatisation Society of Sydney.

PAPER MAKING.—The directors of the Australian Paper Company have purchased, through Messrs. Richardson and Wrench, a portion of the Collingwood Estate, near Liverpool, New South Wales, for the purpose of carrying on the manufacture of paper. The land consists of about 17 acres, and is considered to be admirably situated for that purpose, having an extensive frontage to the George's River, whence an abundant supply of fresh water can be obtained. It can also be connected by a siding with the railway.

Commerce.

CULTIVATION OF TEA IN INDIA.—The recent history of the Indian tea trade furnishes us with an instance of speedy and marvellous development almost without an equal in any department of modern commerce. Forty years have not yet elapsed since Major Bruce first announced his discovery of the tea plant in Assam, and now Indian tea occupies an important place in our import tables, and seems likely eventually to prove one of the great staples of Eastern commerce. When, in 1834, the committee appointed by Lord William Bentinck to report on the best method of cultivating tea in India, with what now appears to us an amusing timidity, recommended the Government to make some experiments on the Himalayan range and on the Neilgherry hills, it was little imagined that in thirty years large tracts of land would be under cultivation, that capital would largely be withdrawn from other, and even European, channels, to be invested in tea plantations, and that so profitable would the speculation be, that persons of rank and position would be found devoting to it their time, their energies, and their fortune. Marvellous, however, as is the recent growth of our Indian tea trade, its ad-

vance has, fortunately, at the same time, been a steadily progressive one. For several years after Lord William Bentinck's committee had ceased to sit, the exports of tea from India were miserably small, and were, indeed, commercially speaking, scarcely perceptible when placed side by side with the gigantic trade of China. The sales of Assam teas in 1847 were only 144,161 lbs., while, three years later, they amounted to 253,427 lbs. The amount of tea exported from Calcutta to Great Britain in the year ending October, 1861, was 1,624,030 lbs.; in the year ending October, 1862, 1,949,866 lbs.; in the year ending October, 1863, 2,724,046 lbs.; while, in the present year, it has risen to 3,343,663 lbs. But if the past has produced such results, what hopes may we not entertain for the future! We believe that we are not exaggerating when we assert that the supply of Indian tea for 1865 will show an increase over the present year of something like 25 per cent.; and when we remember the quality of the commodity itself, and the increasing value which every day's experience attaches to it, we must hesitate before we set down as the dream of an enthusiast, the assertion sometimes made by those interested in the enterprise, that the day will yet come when India may rival even China, and when England may receive not only her cotton, but her tea from her great Eastern dependency. Whatever truth there may be in these anticipations, it is certain that the increase of tea plantations in India must, ere long, produce a marked alteration in the social condition of the population of many parts of that vast empire. A new class of Europeans will be, and, indeed, are already being introduced into India—persons with comparatively small capital, but who are attracted by the enormous profits which are now to be realised by the growth of tea. The advent of these English planters will necessarily introduce a fresh, and, we think, a more healthy element into Anglo-Indian Society, will furnish the stimulus to native industry which is so much required, and will establish centres from which civilization may ultimately permeate the masses of the native population. A few years ago it might have been necessary here to notice and reply to the assertions then so confidently made by some would-be authorities to the effect that the supply we annually receive from China is so nearly all that the British market demands, that no great increase in Indian, or even Chinese production, could ever be made a paying speculation. Exaggerated as it may appear to readers of the present day, it is nevertheless true that Parliament, not so many years ago, was assured, on very distinguished official authority, that it was "more than probable that tea has now reached the limit of consumption in England, and that any reduction of taxation would not augment the use of this innutritious leaf." We need scarcely say that the experience of every year which has elapsed since this rash prophecy was uttered, has shown, in a very decisive manner, the folly of such Parliamentary utterances; and it may now be confidently asserted that, so long as Indian tea preserves its present strength and flavour, there is not the slightest fear of a falling off in the demand, let the supply from China be what it may. Groundless, however, as were such fears, it cannot be denied that there are difficulties which may injuriously affect our great Indian experiment. The *Englishman* recently sounded an alarm which, we believe, will be echoed by those who are well acquainted with the recent course of affairs in the tea provinces of India. The planters in Assam and Cachar find themselves at the present time threatened with the same dangers which in other countries proved fatal to the tea experiment. The labour question is proving the great stumbling-block in the way of ultimate success. We have it on the authority of Sir Emerson Tennent, that the abortive experiment in Ceylon terminated as it did, not on account of any fault connected with the soil or climate, but solely from the want of skilled labour. Again, the failure of the interesting attempt to introduce tea cultivation into South Carolina, made by Dr. Smith, of Greenville, in 1850, must, we believe,

be traced to the same all-important cause. Examples such as these ought to be sufficient to impress us with a sense of the gravity of the present crisis in India. Misunderstandings between the planters and the coolies seem unfortunately to be constant throughout the north-eastern provinces of India, and, so far have matters gone, that the *Englishman* declares that, if something be not done, tea planting in Assam will soon become a losing speculation, and, at last, die out altogether. Without at all endorsing this very sweeping statement, we do not hesitate to say that serious injury may, at the present moment, be inflicted on the material prosperity of India, if some satisfactory settlement of the differences between the contending parties be not speedily arrived at. In every country into which coolie labour has hitherto been introduced very great difficulty has been found in arranging and working out the details of the peculiar contract system which forms the basis of all coolie engagements. The Government authorities have, in most cases, only been too ready to let matters take their own course, and to allow masters and coolies to settle their differences between themselves as they best like. This species of *laissez-faire* policy has, unfortunately, been pursued in Assam and Cachar, and threatens disastrous results. The Indian Government, however, have it in their power to apply a remedy to this state of things, and, by a stringent system of regulations binding fairly and impartially both masters and coolies, to restore while it is yet possible a good understanding between them, and thus save from destruction a rapidly-advancing branch of industry, which, while it is certain to conduce to the material prosperity, will also, we believe, ultimately be found an efficient instrument in the promotion of the moral and social regeneration of our great Indian empire.

Colonies.

SYDNEY FISH.—A collection of young fish from Sydney, consisting of Murray cod and Mauritius carp, have been safely deposited in Berrima River. The collection had been obtained by the Rev. Dr. Hassall from the Acclimatisation Society of Sydney, and by him brought to Berrima, for the purpose of propagation in the Wing Ecarrille.

AILANTHUS SILKWORM.—The following remarks were made by Dr. Bennett, at an ordinary meeting of the Sydney Acclimatisation Society:—Dr. Bennett reported that the ailanthus silkworms recently hatched had all perished. A number had been produced from the eggs sent by Mrs. Devonport from Adelaide. From being unable to procure their natural food at this season of the year, attempts were made to feed them on young lettuce and mulberry leaves, as well as the foliage of the castor oil tree; they eat leaves of the lettuce and white, but not the castor oil tree leaves. The first worms were produced on the 28th June, and the last died on the 19th July. It would be desirable in future to take precautions to prevent their hatching until the season arrives when the ailanthus tree develops its foliage.

COTTON IN QUEENSLAND.—The cotton plantations have been very uncertain in their returns, and in some instances the crops in low situations have been totally destroyed by floods during the picking season, while on others a very profitable yield has rewarded the growers. It is rumoured that one company, established for the purpose of cotton cultivation, are about to abandon the undertaking. With the experience of the past few years as a guide to future operations it is anticipated that the result of next season will finally settle the question as to the profits to be expected from cotton growing in this colony.

NEW ZEALAND.—SEAT OF GOVERNMENT.—A subject which naturally excites a considerable amount of interest is the proposed removal of the seat of government from

Auckland to a site in Cooks Strait. The decision, it is supposed, must lie between the three towns of Wellington, Picton, and Nelson, and the Commissioners who have been appointed to make the selection are expected to reach Nelson very shortly.

NEW ZEALAND TELEGRAPH.—Arrangements are so far advanced for establishing telegraphic communication between all the provinces of these islands that there is no doubt but it will be in full operation next summer. The wire and other apparatus was expected to shortly arrive.

Obituary.

M. GUILLAUMIN, PUBLISHER, PARIS.—This gentleman who was carried off with fearful suddenness by disease of the heart, at the age of 63, held a very eminent position in connection with political economy and cognate matters. He was the founder, or joint founder, of the *Journal des Economistes*, and also of the Political Economy Society, and the publisher of the admirable *Dictionnaire de Commerce*, of the *Annuaire de l'Economie Politique*, and of a large proportion of all the works published of late years on similar subjects. M. Guillaumin was a man of cultivated mind and peculiarly engaging manners, and was, probably, the last representative of a most worthy class of publishers. He resided at his place of business, in the Rue Richelieu, and his house was the resort of all the most eminent political and social economists of the day. He belonged to the liberal party, but he was more remarkable as the friend and patron of all who advocated the removal of restrictions on trade and the amelioration of the condition of the working classes. He was a man of the highest integrity in all his connections, and his death is a loss, not only to the party with which he was connected, but also to France. A large number of eminent men followed the remains to their last home, and M. Passy, formerly Minister of Finance, delivered a simple and most touching address over the tomb, recording the hope that the work which M. Guillaumin had commenced would not die with him. He leaves no successor, his family consisting only of two daughters, who were his beloved companions and fellow-labourers.

Publications Issued.

PRACTICAL DIETARY, FOR FAMILIES, SCHOOLS, AND THE LABOURING CLASSES. By Dr. Edward Smith, F.R.S. (*Walton and Maberley*).—Dr. Smith has been long known to the members of the Society of Arts as an authority on questions of diet, and received one of the Society's medals, in 1861, for papers read by him, and researches made into the influence of alcohols and tea. During the present year the subject of dietary was largely discussed, under his presidency, at the Physiological Section of the British Association, and to that may probably be attributed the publication of this practical work on dietary. There can be no doubt that a work which might be a safe guide to the different classes of the community was much needed—one which should be cheap, and, while written with scientific accuracy, should be simple and practical in its directions. No writer of the present day, probably, possesses more of the qualities needed for such an undertaking than Dr. Smith, and his authority will be generally accepted. The preface informs the reader that "the following work is intended to be a guide to heads of families and schools, in their efforts to properly nourish themselves and those committed to their care; and also to clergymen and other philanthropists who take an interest in the welfare of our labouring population. It is essentially practical and popular in its aim, and therefore contains directions rather than arguments, but at the same time it is based upon the most advanced

state of the science, and, except in the exclusion of many technical terms, is scientific as well as popular. The unusual interest with which the subject of dietary is now regarded, both in a personal and philanthropic point of view, leads to the hope that the publication of this work is not inopportune, and the more so that the Government has lent the most effective aid in the collection of facts, on which it is in fact founded, as shown by the Reports of the Medical Officer of the Privy Council for the years 1862 and 1863, and the press has warmly advocated the importance of the subject. But to clergymen and medical men, more than to others, do the labouring classes look for advice; and much of the usefulness of this and similar works must depend upon their efforts. Ladies, also, may exert the most beneficial influence, and, with a view to aid such efforts, I have added in an appendix certain forms of handbills suited for distribution to the poor." The reader will concur with the author, when he adds that "it cannot be doubted that as dietary is a most necessary and powerful agent in the treatment of disease, so is the due supply of food a chief means of preventing disease and diminishing the burdens of the community. Hence the subject has as much interest to the statesman as to the physician;" and we feel assured that the work in question will be extensively read and do good service.

THE FARM HOMESTEADS OF ENGLAND. By J. Bailey Denton, M. Inst. C.E., F.G.S., Honorary Member of the Royal Agricultural Society of Hanover, and Engineer to the General Land Drainage and Improvement Company. (*Chapman and Hall*). To farm successfully with defective and ill-arranged buildings is no more practicable than to manufacture profitably in scattered, inconvenient workshops, in place of one harmoniously-contrived, completely-fitted mill. No one who is at all acquainted with the farmsteads of Great Britain can fail to be struck with their want of adaptation to the purposes for which they are required. Not only do those which were erected in the last century fail to agree with our improved modes of husbandry, but there will be no exaggeration in saying that they were not suited even to the requirements of those for whom they were built. In former years such buildings might be characterised as a medley of hovels and sheds, thrown together without system. They wanted the merit of convenient arrangement as much as of architectural design. Up to a very recent date, a professional education was considered rather to unfit a man for this branch of art; and the landlord had recourse to local talent, of whatever order it might be. The provincial builder was usually entrusted with the preparation of the plans, in the same way that the blacksmith and wheelwright were looked to for the implements of tillage. He performed this duty with but little reference to the site or character of the farm, and generally upon examples afforded in the neighbourhood. In fact the plan, under the pencil of a parsimonious landlord, was apt to be so curtailed as to be seriously detrimental to the conduct of business; while under that of a landlord used to yield to the whim of a tenant, it was expanded beyond desirable limits. There was not, what we have now arrived at under the stimulation of an imperious necessity, any collection of well-recognised axioms. In quarters where Farm Architecture has ceased to be treated as a mere matter of taste, and where the prosperity of the tenant has been shown to depend in a great measure upon the sufficiency and competence of the accommodation afforded by the homestead, its buildings have been designed with the requisite fitness for the farm, and constructed with a view to durability. Agriculture, in fact, has most properly come to be regarded as a manufacture; and the benefits arising from a perfect adaptation of the farm buildings to the various operations conducted within them are now generally admitted. Much careful attention, in different parts of the country, has of late been given to this subject, and several works have been published, setting forth plans and data of a very valuable description. These, however, have generally contained only the

design of a single architect, and have mostly been issued to create or sustain professional repute. This course might have been followed in the present instance, but the editor has preferred to collect a series of the plans of many different designers, but adapted to the requirements of modern husbandry under all its phases of breeding, feeding, and dairying, in various localities and climates; being strongly impressed with the fact that what the landowner, farmer, and architect now require is an exposition of the leading principles of this branch of constructive art, as they are illustrated by accomplished results on the farms of our foremost agriculturists. Hence the desirability of a work like the present, which collects and records valuable precedents, and professes to give the present state of our knowledge on the subject. The editor has accordingly represented twenty-four specimens of homesteads, the plans being accompanied with descriptive matter not only concerning the buildings, but also the farms upon which they are situated, and the modes of husbandry to which they apply. They embrace covered homesteads, and homesteads distinguished by special accommodation for the rearing and feeding of all descriptions of stock; care having been taken to select examples from farms of various sizes as well as from those characteristic of different localities, in order that persons concerned may study precedents analogous to their particular requirements. It has been found desirable to combine with these plans, drawings of farm-houses and labourers' cottages, together with an illustrated digest of the principles of arrangement and construction which govern the details.

Notes.

POULTRY SHOW IN PARIS.—Five of the *salons* in the *Palais de l'Industrie*, the sides of which were covered a few months since with the productions of the artists of all nations, presented an extraordinary appearance on the 19th, 20th, and 21st instant. In place of history, battles, landscapes, and portraits, were collected the inanimate bodies of fowls, turkeys, geese, and ducks. The exhibition was a great success: there were more than five hundred contributors, and between two and three hundred specimens of poultry of one kind and another. Nineteen departments were represented. The arrangements were admirable; sloping tables were placed around, and double stands of the same kind in the centre of each room. These were covered with blue paper, upon which the poultry was laid out, with ample space on all sides, the various lots, each consisting of four specimens, being separated by filets of wood, painted red, so that every article exhibited could be seen perfectly. On the walls were neatly-painted devices, containing the names of the classes and localities of production, and hung about with laurel, intermingled and enlivened by a few coloured ribbons. The first day was devoted to arrangement; the second, till one o'clock, to the decisions of the jury; after which the public was admitted at a charge of half a franc; and the third to exhibition and sale of the articles. The jury was composed of Comte Léopold Le Hon, President, representative in the Corps Legislatif of the department of Ain, famous for its poultry; two Inspectors-General of Agriculture, four farmers, and four dealers in poultry. The sum of four thousand francs was devoted to prizes, besides medals in gold, silver, and bronze. The grand prize consisted of a large gold medal and a thousand francs. The awards were marked by means of oval cast-iron tablets, painted blue, with the raised letters picked out in gold colour. The fowls were divided into five categories—birds of the races of La Bresse, of La Flèche, of Houdan, of Normandy, and miscellaneous. The first of these was by far the most numerous, as the poultry is the most esteemed. One gold, one silver, and a number of bronze medals and honourable mentions were awarded in

each class, and the grand Prix d'honneur was awarded to M. Gorgondet, of Treffort, in the department of the Aix, for four pullets of the race of La Bresse. The other five classes consisted of turkeys, ducks, geese, pigeons, Guinea fowls, and other poultry. The department of Seine-et-Oise carried off the first and second prizes for turkeys, that of Orne the gold medal for geese, and Rouen the same for ducks. The fowls of La Bresse were not so remarkable for size as for smallness of bone and plumpness; and the manner in which they are prepared for market is quite artistic. Some of the geese were truly gigantic; but the turkeys would not have borne comparison perhaps with those of Leadenhall market. The sale was very brisk, and the names of almost every celebrated gastronomic establishment in Paris were to be seen on tickets in all directions. Forty and fifty francs were asked and easily obtained for prize geese and turkeys; and fowls that had obtained medals were marked in the morning after the exhibition as high, if not higher, than thirty-six francs each. Poultry is an article of great importance in France, and the rearing of fowls in La Bresse, Burgundy, is one of the staple occupations of the locality; but it is not carried on in large establishments, experience proving that the collection of large numbers of poultry in one place invariably gives rise to epidemics amongst them. The Bresse race is not, however, so pure as some others, the delicacy of the meat and the rapidity of the fattening being supposed to depend principally on soil and the mode of feeding. The Bresse pullet can be fattened at the age of three months, while those of other localities cannot be got ready for market till after the fifth or sixth month. The modes of rearing poultry differ in different localities. At La Bresse a pullet of three months is worth about two francs, and the fattening occupies from fifteen to thirty days. To produce what is called a fat pullet takes about five gallons of meal, made from maize and black wheat. This is mixed with curdled milk and given to the poultry in balls; the greater part are, however, only half fattened. A fine fat pullet sells for six to ten francs; an ordinary one for three to five francs at the local market of Bourg. The poultry of the Flèche race is fed in the department of the Sarthe, on barley and black wheat meal mixed in the same way with milk. Four young cocks, for which a prize was given, averaged eleven pounds (English) each, and were valued at 20s. to 24s. each.

SOUTH KENSINGTON MUSEUM "BOXING DAYS."—Since the opening, in 1857, the numbers each year have been as follows:—1857, 5,918; 1858, 9,683; 1859, 8,651; 1860, 5,967; 1861, 9,694; 1862, 5,962; 1863, 8,382. The annual average has thus been 7,750, but on Monday last the numbers exceeded 12,890.

WARMING OF RAILWAY CARRIAGES.—It is reported that experiments in warming carriages by steam have been made on the Royal Eastern line of Prussia, between Bromberg and Thorn, and with complete success. Previously the carriages reserved for ladies were warmed by means of hot sand or stones, but both were found insufficient or objectionable. In the new arrangement, a special boiler is placed in a luggage van, and the steam is conveyed, by means of junction pipes, into wooden cylinders, placed in all the carriages. Each compartment is provided with a small lever, which enables the travellers to regulate the temperature according to their feelings. During the experiments in question the heat was maintained at 22° Reaumur.

FRENCH ACADEMY OF INSCRIPTIONS AND BELLES LETTRES.—Mr. Edward William Lane, of London, has just been elected a corresponding member of this branch of the French Institute, in the place of Baron de Witte, promoted to the rank of Foreign Associate.

GERMAN PICTURES.—At the sale of the library of the late M. Favart, a copy of Lebrun's Gallery of Flemish, Dutch, and German Painters, sold for more than £10. Gilray's caricatures, a rare copy, with the 45 suppressed plates, fetched £8 odd. A curious collection of nearly 100 sketches on vellum and paper, representing Italian and German

costumes, by various artists of the latter half of the 16th and the early part of the 17th century, was sold for £8.

NAPHTHA SPRINGS.—The peninsula of Lenkoran (Asiatic Russia) contains numerous springs of naphtha. No less than 109 are now worked, and yielding annually about 4,000 tons of naphtha, similar to that brought from America. There are also many springs of the kind in the Isle of Taman.

PROPOSED POTTERIES INDUSTRIAL EXHIBITION.—It was suggested at a recent meeting of the committee of the Hanley Mechanics' Institution that an exhibition of the productions of the workmen in that district should be held. The proposal was well received, and a committee was appointed to make the necessary preliminaries. Arrangements have been so far made that it is considered probable that the exhibition will be held in the month of April, and from the active way in which the committee are entering into the undertaking it is likely to prove very successful.

SCHOLASTIC REGISTRATION.—The General Committee for promoting this object, encouraged by the success which has attended the movement in favour of Scholastic Registration, has resolved to convene a public meeting of schoolmasters, and others interested in education, to consider the best means of bringing the question before the Legislature and the public. The meeting will be held, by permission of the Council of the Society of Arts, on Thursday, 5th January, at 2 p.m., at the rooms of the Society, John-street, Adelphi. The Hon. Secretary will read a report of the progress of the movement to this date, and will give an outline of the Medical Act, which has suggested the proposed Act, on a somewhat analogous plan, for the Registration of Schoolmasters and Teachers. Several gentlemen of influence will take part in the meeting; and it is hoped that all promoters of educational reform will endeavour to attend, and co-operate with those whose object is to obtain for the public some protection against incompetent educators, and for the preservation the position to which its character and importance entitle it.

PUBLIC WORKS IN PARIS.—The Prefect of the Seine has just published his annual financial report, and from this and other official sources we learn the cost of the works carried on in Paris during the last twelve years. The amount expended on demolitions, reconstructions, and embellishments, that is to say, on extraordinary, as distinguished from the works of the city, is given as 90,666,627 francs, or, in round numbers, about three millions sterling on an average per annum. Of this total the city of Paris has supplied rather more than two-thirds, and the State less than a tenth; the balance being derived from a resale of land and other miscellaneous sources. The 900 and odd millions have been divided amongst various works in the following proportion:—Nearly 33 millions for charitable objects; religious edifices, upwards of 32 millions; municipal buildings and schools, more than 64 millions; the great market, nearly 12 millions; bridges and roads, nearly 50 millions; formation of new boulevards and streets, 590½ millions; extension of Paris to the fortifications, including the removal of the *Ortoi* wall and gates, and construction of the new barriers, nearly 130 millions of francs. In 1859 Paris was lighted by 14,911 gas lamps, and the banlieue by 2,812 gas and 750 oil, making a total of 18,939 lights, now increased to 30,295. The great system of drainage is approaching its conclusion; and in the month of May next Paris will have its new river in the canal which is being constructed to bring the waters of the Dhuise to the capital; artesian wells have been sunk; large reservoirs for the supply of the city have been formed in the outskirts; half the theatres have been rebuilt; the parks and promenades have been planted and improved; many public squares have been planted and thrown open to the public; new roads and streets have been formed, and many old ones widened, ventilated, and otherwise improved. This is certainly a vast amount of work to have been done in a

dozen years, even under the extraordinary circumstances of the case; and it is astonishing that even the immense sum given in the report in question should have been half sufficient for what has been performed. One of the most important, nay, the most important result attributed to the improved condition of the city is the reduction of the rate of mortality. In 1836, when the first quinquennial census was made in France upon the present system, the deaths were 2.78 per cent., or in the proportion of one in 36 inhabitants annually; in 1841 and 1846 the rate was nearly the same; but in 1856 it had fallen to 1 in 39; and it now stood at about 1 in 40. With respect to future works a commission has been appointed to draw up a general programme based on the following questions:—What buildings require re-building or enlargement to meet the necessities of the public service? What will be the expense of each? and What is the degree of urgency of each, and in what order should they be undertaken?

STEAM OMNIBUS.—Nantes was the birth-place of the omnibus, and to this day the original arrangement of a conductress swinging in a basket at the back is adhered to, and having been the first to supply horse flesh to the million, that busy town seems bent upon setting aside her own former pet in favour of a new one. A steam locomotive, with passenger carriages attached, has for some time attracted great attention in that place, and the accounts published are highly laudatory. The new conveyance is the invention of M. Lotz, an engineer of Nantes, and it has obtained the attention of the authorities. A short time since, at the request of the Prefect of the Department, the locomotive, with a *char-à-bancs* and an omnibus attached, was driven into the yard of the prefecture, where, it is said, it was turned round and moved about with singular facility. The Prefect and some few other gentlemen then entered one of the carriages, and the train was conducted through the streets of the town and towards the Paris road. At first the pace was that of an ordinary trotting horse, but when outside the town this was increased to more than sixteen kilometres—nine and a-half miles an hour. It is reported that the mode of attachment adopted by M. Lotz is so good that the locomotive, with two carriages in its train, turns in a circle of about thirty feet in diameter. If these reports be not a little too highly coloured, M. Lotz has been more successful than other engineers who have attempted the application of steam for ordinary traffic. And even supposing the triumph to be achieved, the question of cost still remains to be answered.

ELECTRO-MAGNETIC LOCOMOTIVE.—At a meeting of the Scientific Society of the Department of the Seine-et-Oise, held at Versailles a few days since, a model of an electro-magnetic locomotive was exhibited and explained by its inventors, MM. Bellet and De Rouvre. This new engine is intended to run on rails, and the arrangement of its parts is somewhat curious. The driving power is given to a single pair of wheels situated at the rear of the engine, as in the Crampton engines. A number of magnets are arranged radially on these wheels, their poles towards the circumference; the voltaic current is conducted from the centre of each wheel to all the magnets in succession, and these latter act directly on the iron rail itself. The inventors claim for their engine the great advantage of excessive simplicity, and moreover, that as the magnets act directly on the rails, there is a constant amount of adherence, which does away with the necessity of weight to ensure safety even with the highest speed possible. The inventors seem to have specially in view the postal and telegraphic service. They say:—"This machine may be employed to carry letters and parcels in the interior of towns at the rate of twelve or fourteen miles an hour, on subterranean railroads, connecting the principal post-offices; and as the locomotives for such service would be very small, the works would be comparatively inexpensive. Larger machines might run on the existing railroads, and convey despatches at the rate of a hundred and twenty miles an hour." The machine is

ingenious, and doubtless works well in a model, but it remains to be seen whether it would be practical on a larger scale.

THE ATLANTIC CABLE.—The entire length of the Atlantic telegraph will be 2,300 miles. There are seven copper wires to form the conductor, so that there are 16,000 miles of copper wire. Every portion of this wire is subjected to electrical tests to ascertain its quality for conduction before it is allowed to be worked up. The next stage is to coat these with eight successive coats of the insulating material, equal to an aggregate length of 18,400 miles. This core is next covered with jute wound round it from ten strands, making 23,000 miles of jute yarn. Then comes the outer coating formed of the ten covered iron wires. The iron wire itself is 23,000 miles in length, and each wire is covered separately with five strands of tarred hemp, 135,000 miles of the latter being required, making together an aggregate length of material employed of 215,000 miles.

CHINESE AND JAPANESE WORKS.—A remarkable sale of Chinese and Japanese curiosities, stated to be the property of Mr. Marks, of London, took place in Paris on the 29th November. Two large garden stools, or table bearers, in incised enamel work, ornamented with flowers on a blue ground, fetched £248. A fine four-sided vase, of the same character, decorated with landscapes, kiosts, and scenes of industry, was sold for more than £68. A rock crystal ball, about 16 and 17 inches in circumference, realized upwards of £52. Five pieces of Chinese enamelled ware, ornamented with flowers and birds, the vases being about 13 inches high, sold for £108. Two vases in old Japan porcelain, 33 inches high, decorated with landscapes and flowers, in blue, red, and gold, realized nearly £59. A vase of old Chinese porcelain, decorated with agricultural scenes, rather more than 13 inches high, fetched nearly £44. And two vases of the same manufacture, with cameos of figures, animals, and flowers, in blue on a white ground, £60. The day's sale produced 42,868 francs (£1,715 nearly).

Patents.

From Commissioners of Patents Journal, December 23rd.

GRANTS OF PROVISIONAL PROTECTION.

Aeriform fluids, &c., obtaining motive power from—3044—M. P. W. Boulton.
 Artificial fuel, compounding by agglomeration—2920—G. M. de Bayelt and J. E. Vigoulet.
 Reer engines, works and cases of—2869—R. G. Grimes.
 Belt and sanitary apparatus—3034—W. E. Gedge.
 Bridges, construction of—3069—A. J. Sedley.

Casks—3002—C. Smith and W. Fletcher.
 Coal and coke, separating sulphur from—2998—C. Binks.
 Coals, &c., revolving retorts for producing oil from—3020—J. G. Winter.
 Cotton, ginning or cleaning—2982—E. W. Otway.
 Cotton pieces in the gray, apparatus for finishing—2933—J. Eastwood and W. Wadsworth.
 Electric fire buttons and indicators—2997—J. Sax.
 Felt, manufacture of—3046—R. Richardson.
 Fibrous substances, apparatus for preparing, &c.—3063—M. J. Roberts.
 Fire-arms, breech-loading—3001—T. Wilson.
 Fire-arms, &c.—2892—J. G. Tongue.
 Gases, apparatus for the production of—3018—C. W. Siemens.
 Gunpowder, &c., prevention of the accidental explosion of—3017—J. G. Ulrich.
 Hair brush, mechanical—2999—J. Neat.
 Hand stamps—3028—W. E. Newton.
 Hollow ware, moulds for casting—3097—J. Crowley.
 Human hair, apparatus used when brushing—3085—A. Brittlebank.
 Iron, manufacture of—3071—J. Vaughan.
 Jacquard machine—3105—J. and J. Leeming, and J. Lister.
 Japanned ware and furniture, decoration of—3054—A. Smith.
 Lighthouses, &c., apparatus for sounding bells on—3057—C. Oliver.
 Meat, &c., rooms and places for curing and preserving—2995—T. Harris.
 Metal tubes, &c., solid and seamless—3091—J. Barnaley.
 Neck collars—2967—S. S. Maurice.
 Ornamental fabrics, production of—3012—J. K. Crawford.
 Photo sculpture—3107—A. F. J. Claudet.
 Pumps—3021—H. Wilson.
 Railway carriages, apparatus for enabling the guard to keep all the doors closed until the train is to a stand-still—3067—J. Holly.
 Railway carriages, locking and unlocking the doors of—3024—K. Shaw.
 Railways and tramways—3061—W. A. Adams.
 Ruche for chenille and upholsterer's trimmings—3036—G. Dixon.
 Ships, propellers for—2996—J. Taylor.
 Signals, railway carriage and passenger—3016—J. W. Proffitt.
 Silver, &c., coating iron and steel with—3095—J. B. Thompson.
 Sliding gaoliers, &c.—3022—R. Tye.
 Smoke consuming apparatus—3032—A. Biampoli.
 Sound, apparatus for rendering inaudible—3000—F. C. Rein.
 Spring mattresses, folding—3004—S. P. Kittle.
 Steam boilers—3052—W. Husband and J. Quick, jun.
 Stones, &c., apparatus for breaking—3038—T. Archer, jun.
 Submarine explosives, conveying and exploding—2562—W. M. Ryer.
 Textile fabrics, manufacture of—3008—W. Pollock.
 Throistle spinning, &c., apparatus for effecting the drag in—3067—A. Pemberton and J. Ford.
 Travelling, combined stretcher, bed, cushion, and wrapper for—3040—A. H. Robinson.
 Vegetable substances, obtaining extracts from—3101—P. F. Lunde.
 Weights, raising and lowering—2993—J. Soper.
 Wet gas meters—3059—E. Myers.

INVENTION WITH COMPLETE SPECIFICATION FILED.

Straw hats, &c., shaping and pressing—3099—G. W. Belding and D. E. Holman.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

JAN. 18.—“On the Best Mode of Applying Power to Propel Trains, on the Metropolitan and other Railways, having Frequent Stations.” By PETER W. BARLOW, Esq., F.R.S.

JAN. 25.—“On the Best System for Extinguishing Fires in London.” By FREDK. YOUNG, Esq.

FEB. 1.—“On London Sewage, from the Agricultural Point of View.” By J. CHALMERS MORTON, Esq.

CANTOR LECTURES.

“ON THE REPRODUCTION OF NATURAL FORMS BY ART AND MANUFACTURE.” By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

Mr. Hawkins will resume his Course, on Monday Evenings, as follows:—

JAN. 16TH, 1865.—LECTURE III.—On the varieties of artistic treatment of the forms of animal and vegetable life—pictorial representation; conventional ornamental, allegorical, and symbolic combinations of animal forms.

JAN. 23RD.—LECTURE IV.—On the fitness of designs, and their adaptation to the conditions of the materials in which they are to be produced. (Demonstrated by metal-work processes, sand-moulding, casting, and chasing).

JAN. 30TH.—LECTURE V.—On Ceramic Manufactures, with the Influence of the material on the design and its successful production—modern Terra-Cotta, Della Robbia ware, Majolica, and Faïence.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture. A set of tickets for this purpose has been sent to every member.

PRIZES TO ART-WORKMEN.

The following is a Catalogue of the works sent in competition:—

FIRST DIVISION.

WORKS EXECUTED FROM PRESCRIBED DESIGNS.

- No. 1. Carving in Stone of Boy and Dolphin. By “Lennox.” Price £18.
2. Ditto in Marble. By “S.” Price £15.
3. Ditto in Stone. By George H. Ives.
4. Ditto in Marble. By John Willis, 20, Elizabeth-street South, Pimlico, S.W. Price £15.
5. Carving in Wood of Chair-back. By James Stuart, 7, Pancras-square, N.W. Price £10.
6. Carving in Stone, after a Gothic Bracket. By W. Weaver, at R. Boulton’s, Sculptor, Worcester.
7. Ditto in Stone. By “eo.” Price £8.
8. Ditto in Stone. By “Leon.” Price £8.
9. Carving in Wood of an Inkstand. By. W. H. Baylis, 69, Judd-street, W.C. Price £50.
10. Carving in Wood of a Harp-head. By T. E. Mayle, 17, James-street, Camberwell New-road, S. Price (completed) £15 10s.
11. Raphael’s Three Graces, Repoussé Work in Metal. By W. Holliday, 14, Nailour-street, Islington, N. Price £16.
12. Ditto. By E. Beresford, 7, Chapel-street, Pentonville-road, N. Price £10.
13. Ditto. By C. Jacquard, 1, St. George’s-road, New Kent-road, S.E. Price £8.
14. Ditto. By Thomas Bayley, Rann-street, Ladywood, Birmingham.
15. Repoussé Work in Metal, after a Flemish Salver. By Septimus Beresford, 29, Myddelton-street, E.C. Price £8 8s.
16. Ditto. By W. Ash, 54, Wych-street, W.C. Price (completed) £7 7s.
17. Ditto. By H. R. Batchelor, 149, St. John’s-street-road, E.C. Price £18.
18. Hammered Work in Iron, after a Pediment of a Gate; designed for use as a bracket. By W. Letheren, Lansdown Iron Works, Cheltenham. Price £1 15s.
19. Ditto. By T. Winstanley, 10, Arthur-street, New Oxford-street, W.
20. Ditto in brass of the same. By J. Z.
21. Child sleeping, carved in Ivory. By J. W. Bentley, 22, Sherwood-street, Golden-square, W. Price £20.
22. Ditto. By John Richards.

23. Chasing in Bronze of "Clytie." By T. Nichols, 4, Everilda-street, Hemingford-road, N. Price £15.
24. Ornament chased in Bronze. By R. Orpwood, 2, Richmond-road, Park-road, Islington, N. Price £15.
25. Ditto. By R. E. Barrett, 26, Harrison-street, Gray's Inn-road, W.C. Price £15.
26. Ditto. By R. Reynolds, 15, Oak-village, Kentish Town, N.W. Price £12 12s.
27. Ditto. By A. Barrett, 26, Harrison-street, Gray's Inn-road, W.C.
28. Ditto. By S. R. Meek, 26, Harrison-street, Gray's Inn-road, W.C. Price £15.
29. Ditto. By V. F. Howe, 23, Berners-street, W. Price £10.
30. Ditto. By H. J. Hatfield, 16, Alfred-street, Tottenham-court-road, W. Price £10 10s.
31. Ditto. By H. R. Batchelor, jun., 149, St. John-street-road, E.C. Price £10.
33. Ditto. By S. Dawtry, 2, Walker-street, Infirmary-road, Sheffield.
34. Engraving on Silver of an Arabesque, by Lucas Van Leyden. By Gilles Mackenzie, 12, Tudor-street, Sheffield. Price £6.
35. Ditto on Copper. By G. S. Berry, 26, Warwick-street, Regent-street, W. Price £2 10s.
36. Painting on Porcelain of the Two Children in Raphael's Cartoon of "Lystra." By X. Designed for a door-plate. Price for the set of two plates and handles, £10.
37. Ditto. A Plate. By T. R. Price £10.
38. Ditto. A Plate. By H. Price £10.
39. Ditto. By Joseph B. Evans, South-street, Mount Pleasant, Fenton Potteries.
40. Ditto. By W. J. Goode, South Audley-street, W.
41. Ditto. By E. E. Dunn, Milner-street, Bethesda-street, Hanley, Potteries. Price £5.
42. Ditto. By Stephen Lawton, Backnell Old-road, Hanley, Potteries.
43. Painting on Porcelain of an Arabesque, by Lucas Van Leyden. By Joseph B. Evans, South-street, Mount Pleasant, Fenton, Potteries. Price £10 10s.
44. Ditto. By George Griffiths, 22, Castle-street, Newcastle-under-Lyne.
45. Decorative painting. By Robert Yarrow, 67, Herbert-street, New North-road, N. Price £3 10s.
46. Ditto. By John Henk, George-street, Stoke-upon-Trent. Price £2.
47. Inlay in Metal. By E. A. Millward, 35, Little Clarendon-street, Somers-town, N.W.
48. Cameo cutting. Human Head. By James Ronca, 156, King's-road, Chelsea, S.W. Price £8.
49. Ditto. By "H. S." Price £12 12s.
50. Ditto "St. George and Dragon." By James Ronca, 156, King's-road, Chelsea, S.W. Price £8.
51. Wall Mosaics. Human Head, after *Bertini*, of Milan. By "Nemo."
52. Ditto. By the same.
53. Ditto. By J. H. Stevens, Lambeth Glass Works, Carlisle-street, S. Price £25.
54. Ditto. By Samuel Cooper, Longfield-place, Hartshill, Stoke-on-Trent. Price £10.
55. Gem Engraving. Human Head. By E. H. Renton, 34, Percy-street, Bedford-square, W.C.
56. Ditto. By John Wilson, 14, Leicester-place, W.C.
57. Ditto. By A. Warner, 18, Newman-street, W.
58. Ditto. Full-length Figure. By John Wilson, 14, Leicester-place, W.C.
59. Die Sinking. Head of Prince Consort. By Henry Allen, Franchise-street, Birchfield, near Birmingham.
60. Ditto. By John Parkes, Nursery-lane, Harbourn, near Birmingham.

61. Ditto. By John Hatchett, 5, Gloster-terrace, Kennington-park, S.
62. Ditto. By George T. Morgan, Regent-place, Wheeler-street, Loyella, Birmingham. Price £2.
63. Ditto. By W. A. Walker, 14, Montpelier-place, Brompton, S.W. Price £10.
64. Bookbinding after an Italian Specimen. By Louis Gentil, 15, Broad-court, Bow-street, W.C. Price £8 8s.

SECOND DIVISION (WOOD-CARVING).

WORKS EXECUTED WITHOUT PRESCRIBED DESIGNS.

SECTION A.

Human figure in alto or bas relief. Animals or natural foliage may be used as accessories.

67. "Spring"; a Child's Head. By Mark Rogers, 111, Tachbrook-street, S.W. Price £10.
71. Bas-relief, in rosewood. By W. M. Holmes, 101, Dean-street, Soho, W. Price £2 15s.
72. Ditto. ditto. By the same. Price £2 15s.
77. Female Figure, in Oak. By Charles Liddle, 72, Pancras-square, N.W. Price £30.
78. "Hope for the Future." By T. W. Wallis, Louth. Price £31 10s.
83. "Repose." By E. Brew, 73, Sankey-street, Warrington. Price £5.
84. "Caractacus." By G. R.
86. Nymph and Loves. By G. F. Bridge, 3, Vincent-square, S.W. Price £7 7s.
86. "Morning." By same. Price £1 10s.
88. Door for an Ebony Cabinet. By E. Glancy, Rose-cottage, Alexandra-terrace, King's-road, S.W. Price £18.
89. John and the Mother of Christ. By J. W. Gould, 83, Bayham-place, Camden-town, N.W.
91. Cain preparing his sacrifice. By James Griffiths, 8, Addington-place, York-road, S. Price £20.

SECTION B.

Animal or still-life. Fruit, flowers, or natural foliage may be used as accessories.

66. Chimney Piece. By Miss Maude, care of F. H. Simpson, Esq., 34, Fore-street, E.C. Price £31 10s.
69. Envelope Case and Blotting Book. Walnut Wood. By T. Hewitson, 5, Hatton-garden, E.C. Price £16 16s.
- 74 and 75. Panels for a Sideboard or Cabinet. Walnut Wood. By W. J. Gibson, 94, Star-street, Edgeware-road, W. Price £14 the pair.
79. Wagtail and Fly. By T. W. Wallis, Louth. Price £21.
81. Panel of Flowers and Birds. By " " "

SECTION C.

Natural foliage, fruit, or flowers, or conventional ornament in which grotesque figures or animals may form accessories, preference being given where the work is of an applied character for ordinary decorative purposes, as representing commercial value.

65. Portion of Frieze. By George Murray, 6, Claremont-place, Henderson-row, Edinburgh. Price £14.
68. Vase, carved in Boxwood. By John Manhood, 37, Berwick-street, Pimlico, S.W.
70. Envelope Case and Blotting Book. Sycamore. By T. Hewitson, 5, Hatton-garden, E.C. Price £10 10s.
73. Tripod Stand. By W. M. Holmes, 101, Dean-street, Soho, W. Price £12.
76. Pair of carved frames. By George Bull, 8, Chalton-street, Euston-square, N.W. Price £14 the pair.

Fragment of Autumn. By T. W. Wallis, 10th. Price £7.

Panel. Walnut wood. By W. Taylor, 21, Newmarket-street, W. Price £6 6s.

Panel with Double Festoon, and three drops of red flowers. By George Lock, 26, Albert-street, Camden-town, N.W. Price £50.

Ze. By T. R. Smith, 7, Clarence-gardens, Kent's-park, N.W. Price (completed) £8.

HUMAN FIGURE IN RELIEF.

Temptation. By Gerrard Robinson, 14, Theobald-street, Manchester-square, W. Price £30.

Libaldi. By the same. Price £16.

Water. By the same. Price £16.

The Grinder. By the same. Price £15.

Shakespeare. By the same. Price £16.

Barber. By the same. Price £16.

Spring Child, carved in alabaster. By S. F. Ridge, 3, Vincent-square, S.W. Price £5 5s.

Proceedings of the Society.

ART-WORKMANSHIP COMPETITION.

A meeting was held on Monday evening, the 4th of January, at which the exhibitors and friends were specially invited to attend. At 7 o'clock the chair was taken by Wm. E. Esq., who, in opening the meeting, said—The object which the Council had in view in calling the present meeting was to confer with the workmen themselves upon the system of Art-Workmanship as inaugurated by this Society, and to receive suggestions for carrying them out more effectually. He explained the nature of the examinations given by this Society in connection with the Union of Art Institutes, by means of which young men had an opportunity of displaying their knowledge and proficiency in various branches of learning, and thus receiving a stimulus to exert themselves in carrying on their education after leaving school.] In like manner the Society had initiated these competitions, in which the workmen could exhibit the results of their skill and proficiency in various branches of handicraft of an artistic character. He regretted that so small a number of persons had availed themselves of it, and that so few works had been sent in. He had been told that it arose mainly from the fact that the workmen had been so much employed during the year as to have but little leisure to attend to work in the evening. If this were so it was a healthy sign. He had been told that in selecting the examples the Council had not sufficiently attended to the point that the articles exhibited should have a saleable character, and, that not sufficient publicity had been given to the competition, so that the various trades were not generally made aware of it. Whether that were so or not he could not say; but means had been taken, by the distribution of programmes in the workshops, to make the competition known, and he would be done in this direction next year if it were necessary. As it was, however, upwards of 600 persons had purchased examples at the Society's house. He well known that, in 1851, the Exhibition showed that this country was inart-workmen. In 1862, the Exhibition showed a very marked improvement in this direction, and the French Government sent over a Commission to enquire into the causes of it. He (the Chairman) believed might be attributed mainly to the efforts made at Birmingham, by means of schools of design and to improve the art-education of the people. It was, however, much still necessary to be done, and the Society of Arts stepped in, by the offer of prizes, to do as it could, in stimulating progress, and to do

this in a manner not taken up by the Government. He would now ask the meeting to discuss freely the system established by the Society of Arts, and the Council would be glad to hear suggestions and criticisms from any of the working men present. The Council had been told in some quarters that the time laid down in the programme for the execution of the works had not been sufficient, and that the prescribing of designs had fettered the workman, who ought to be left free to exercise his genius and his fancy as he liked. In this he would reply, that though prescribed designs were included in the conditions relating to one portion of the programme, yet, as regards wood-carving, there was a department in which the workman was left free to do as he pleased. On these and various other points he would ask the meeting to express their views.

Mr. NICHOLS (silver chaser) said, in his opinion, it was beneficial that the Council should select and prescribe designs as they had hitherto done. He suggested that the decision as to prizes should be given as soon as possible after the works were sent in. He thought a twelvemonth ample time for the execution of the works for competition, but hoped that more publicity would in future be given. He suggested that in the selection of the designs and examples by the Council advice might with advantage be taken from some of the workmen, both as to the nature of the subjects and the nature and amounts of the prizes.

Mr. Mc KENZIE (silver engraver) said he had come expressly from Sheffield to attend this meeting. He thought, as far as his own trade was concerned, ample time was given. Trade had been good during the year, and left the men little leisure for this work in overtime, and this he considered might account for the small number of works sent in.

Mr. MACKIE (wood-carver) said the men had been too busy this year to give time to the competition. He thought a twelvemonth's time would be best, but certainly nothing less than six months should be given. The total amount of prizes offered was ample, but, in his opinion, the prizes should be small and more numerous, as likely to attract a larger number of competitors. He advised drawing and modelling to be added to the list for which prizes should be offered.

Mr. BAKER (wood-carver) objected to competitions of this character. The present exhibition was like other exhibitions of a similar character, a failure. ("No, no.") He repeated it was a failure, for in many branches there was but one work sent in. Such a state of things could scarcely be called a competition. It must be a failure, because it was impossible for a man who had been hard at work all day to do justice either to himself or to his work in overtime. He then proceeded to remark upon some observations which had appeared in the Society's *Journal*, commenting upon the Society's programme of the competition, as by no means warranted, and which he thought were likely to discourage the workmen from competing. These exhibitions, if honest, had a tendency to distinguish the counterfeit from the real, and in so far as they did this they were beneficial. He was, however, afraid they were frequently not honest. It was well known that numbers of good men worked for others, and their works were shown probably as the work of one man, who reaped all the honour and benefit, whilst the man who actually deserved to be rewarded was passed by and lost. Let the Society take steps for catching the men of genius themselves, so that they might become known to the world. The working man of genius wanted something more than prizes—he wanted fame.

Mr. H. COLLE, C.B., said he was glad there was some opposition displayed, for if they were all of one mind he feared that there would little good come of the discussion. He thought the objection that the Council were only offering money prizes, and not fame, scarcely correct. In one division of the competition the wood-carvers were free from all and could

exercise their genius and talent in any manner they liked. He did not agree with the last speaker that the present exhibition was a failure. He thought the present competition by no means unsatisfactory. The execution of the work showed a decided advance over that of last year. He, however, agreed with one of the speakers as to the importance of drawing and modelling, but he did not think, therefore, that they ought to be included in the Society's offer of prizes. It should be recollected that the competition was in art-workmanship; and, as far as drawing and modelling were concerned, there was plenty of competition in each at South Kensington, where prizes and medals were largely given in both subjects. The schools in which these were taught, and where government prizes might be obtained, were easy of access, and at very trifling fees, in every part of the metropolis. Original design required other qualities than art-workmanship did, though no doubt an art-workman was all the better if he could draw, and better still if he could design. For design the government offered rewards, but he did not consider it the duty of government to offer prizes for art-workmanship; that duty he thought properly devolved upon the Society of Arts. He did not agree with those who advised the bringing in as judges persons connected with the trade; he, on the contrary, thought it extremely important that the judges should be men thoroughly independent of all connection with the trade.

Mr. STEWART HARRISON (a builder) thought exhibitions of this character were contrary to the spirit of the age, an age which sought rather to convert men into mere machines. The cry for cheapness was the cause of this. One man alone could do nothing; each man was kept to one portion of a work alone. He knew an instance where a man was kept from one year's end to another carving egg and tongue mouldings, and did nothing else. He was permitted to have no other aspiration; his energies and talent were cramped and confined. The movement now taken up by the Society was in the right direction to counteract this debasing influence, and the Council were engaged in a great and noble work.

Mr. P. GRAHAM—If the exhibition was small, it was gratifying to hear that it was caused by the full employment of the workpeople. The Council were glad to have the opportunity of hearing the various opinions of the working men, and diversity of opinion could not fail to be attended with benefit. One thing, however, was clear, that in speaking of the time necessary to be allowed to competitors for executing their work, the period would always depend on the state of trade, as affecting the leisure of the workman. He could, from his own experience, confirm the statement as to the full employment of the men last year, and he was not surprised at the smallness of the exhibition, but, on the contrary, he was surprised there were so many works sent in. All the observations which had been made that evening went to show that the Society was on the right track, but time was required to develop the scheme. There was some diversity of opinion as to the amount of the prizes. He thought the present scale was the right one. No doubt a larger number of smaller prizes might produce more works, but he thought of less value.

Mr. LETHEREN (smith)—If there were disadvantages affecting the workmen in London, they were nothing as compared with those affecting the workmen in the country. The former had opportunities of inspecting the actual works themselves, whilst the country workman must content himself with the photographs or casts. As regarded amount of overtime at the disposal of the workman, he thought this depended much on the man himself. Where there was a will there was a way. He spoke as a smith, and all knew that a smith's work was not of a very light character. All the work he had sent in was done in overtime. He questioned very much what had been said by one of the speakers as to the work of men being sent in as the masters'.

Mr. ALLEN (a coachmaker) was not aware till within

the last few days that there was any such competition or exhibition as the present. He thought sufficient publicity had not been given to it. In his opinion, however, the evening labour of men in their overtime was not likely to produce good results. He thought, too, that the working men who had ideas would be chary of displaying their designs and giving them to the public.

The CHAIRMAN said it must be remembered that, as regarded one division of the programme, the examples were from approved and selected works, and were supplied to the workmen, whilst in another division the wood-carvers had full scope for display of their invention, genius, and talent. He thought that the workman need not be afraid of exhibiting his design, for he felt assured that if it displayed talent it would lead to employment. The great principle on which the whole competition was based, was that of bringing out the talent of the individual workman himself. Such a competition as this distinguished the counterfeit from the true. As to the time for execution, last year it extended from February to November, and, from all he had heard that evening, he concluded it was sufficient. He was not disappointed at the result of the present year's Exhibition, it was in the nature of such movements to be small at first, and he felt assured they would grow. Take the Examinations of the Society, commenced seven years ago with 52 candidates, whilst last year the candidates examined had amounted to 1,200. He did not agree with the remark that competition was injurious. He was glad to see so good an attendance that evening, and in the name of the Council expressed the pleasure it afforded them of meeting the workmen, and hearing their observations, which he was sure would meet with every consideration. The competition would be renewed next year, he hoped, on a more extended scale, and every means would be taken to ensure its being made known to those interested, and he had every confidence it would be well responded to.

The meeting then adjourned, and tea and coffee were served in the library.

Proceedings of Institutions.

MACCLESFIELD USEFUL KNOWLEDGE SOCIETY.—The annual meeting and distribution of prizes of this society took place in the Town Hall, on the 8th of November, being the 29th anniversary. E. C. Egerton, Esq., M.P., one of the Vice-Presidents of the Society, took the chair, and observed he was glad to be able to congratulate the committee of the Institution on the increased strength of, and attendance at, the female and juvenile classes. At the same time it was a matter of deep regret that the society—but more particularly, perhaps, that department relating to the School of Design, did not receive that amount of support which it was entitled to, considering the peculiar circumstances of the town and the nature of the manufactures carried on within it, and considering, too, the fact that the prosperity of the town was dependent in a great measure upon the beauty of the design of its fabrics. Among the students to whom prizes would be awarded were those who had gained honours in connection with the School of Design, and it was in regard to that department of the Institution that he wished to say a few words. The meeting was no doubt aware that during the last session of Parliament a committee had been sitting upon the subject of Schools of Design. Many complaints had been made in various parts of the country, that of the large sum of money asked from Parliament, amounting to £100,000 for Schools of Art, a very great proportion was absorbed in the South Kensington Museum, and that only a very small sum indeed found its way into the provinces. The mode of payment, too, adopted by the Government, excited a great deal of discontent on the part of many masters of

f Design. Instead of paying, as formerly, on carrying with them a payment of £10 each (one sometimes having as many as five), government ed to pay on what they called "results," these sing confined to the number of medals taken by an class. One evil arising from this mode of pay- a, that it excluded those Schools of Design that include among their members students of the ar- m, and it was in consequence of the many com- made that a committee of the House of Commons pnted, of which he had the honour of being a e. That committee sat two months during the im, and any one who would take the trouble to look : blue book relating to it would find there a good valuable and interesting information. They would whole history of Schools of Design from their first sement, and the testimony given of them by such Sir Charles Eastlake, Dr. Maclise, and other prac- m of science and art; at the same time he (the m) was bound to admit that the weight of evidence sint the alteration proposed by the government. ut increase which had taken place in the Schools since their establishment was something amazing. l the whole cost of the several Schools of Design in and the provinces amounted to about £15,000; w nearly £90,000; and the question very naturally re the results equal to this large outlay? He l he should be justified in saying that the country ived substantial benefits in the shape not only of tastes among the artisan class, but more intellec- sements, which had exercised a beneficial influence the middle and the working classes, and much of believed was attributable to Schools of Design, and ion such as that in support of which they were met ing. The Honorary Secretary next read the re- During the past year the number of members has -Honorary, 198; ordinary, 189; female and junior s of classes, 113; making a total of 500. The re constituted as follows:—

	Teacher.	Ave. Att.	No. on Books
etic	Mr. S. Wood ...	25	46
g and Writing...	Mr. Botheras ...	16	52
ar	Mr. Barber	13	22
phy and History	Mr. Botheras ...	12	49
stry	Mr. Wire	—	—
.....	M. Dumont... ..	7	—
.....	Mr. Hambleton	15	20
Female.			
al Instruction ...	Mr. Malburn ...	26 }	45
.....	Mrs. T. Jeffery	17 }	
Juvenile.			
al Instruction ...	Mr. Malburn, jun.	38	70

Committee have great pleasure in noticing the im- al state of the classes, and especially rejoice in the final prosperity of the junior class, because they ve that the chief good here obtained is not so much is amount of knowledge gained as in the mental : induced, and yet still more in the moral habits in- through these. During the past year the students passed through three examinations—the first, that of elisty of Arts in its preliminary and final stages; the l, that of the Government Department of Science rt; and the third, our own, conducted by the mem- f the Class Committee. The circulation of the in the library has been 11,500 volumes, a less num- an during the year 1868; but the committee are d to report that the works read have been of a higher ter than of late years, literature of a scientific class : been much more in demand. Only about 50 s have been added to the library. During the past eral lectures and entertainments have been pro- y the Committee: J. C. Buckmaster, Esq., B.A., delivered a lecture upon "The Advantages of a age of Science and Art;" the Rev. J. J. Wray, a

lecture upon "Venice;" a concert under the conduct of Mr. Ellis Roberts, harpist to H.R.H. the Prince of Wales; a dramatical and musical entertainment, kindly given in aid of the society by Messrs. Nosworthy, Smith, and Gregory, of the Manchester Amateur Societies; and more lately, a concert conducted by Mr. Twiss. These lec- tures and concerts have proved more successful than those held for some time previously. The committee having noticed the success of the "Penny Readings" in the town, and having learnt that they were not to be continued this season, decided to arrange a series of "Monday Popular Entertainments," which should in a measure aim to serve the same good purpose, and also aid in bringing the So- ciety more constantly before the notice of the public. Three of these entertainments have been held, each one attended by a numerous and interested audience. The committee cannot, however, forbear naming how far thei efforts in this direction are partially frustrated by the wan of a suitable music and lecture hall.

DUBLIN INTERNATIONAL EXHIBITION, 1865.

Scotland has taken up representation at the Dublin Ex- hibition with characteristic energy. The Provosts and Chief Magistrates of Edinburgh, Leith, Dundee, and Aberdeen, &c., head the movement. It is expected that Edinburgh will send as much to Dublin as to the last London Interna- tional Exhibition. The Committee at Edinburgh includes the following influential persons:—The Lord Provost, Bailie Cassels, Bailie Alexander, Bailie Hill, Bailie Handyside, Bailie Falshaw, Bailie Miller, George Lorimer, Henry Callender, Adam Beattie, Charles Macgibbon, James MacKnight, John Kay, Thomas Dryborough, James Ford, the Master of the Merchant Company, the Chairman of the Chamber of Commerce, the Dean of the Faculty of Advocates, the Deputy Keeper of the Signet, the Preses of the Society of S.S.G., the Preses of the Society of Chartered Accountants, the Presidents of the Royal Scottish Academy, of the Royal Scottish Society of Arts, of the Royal College of Physicians, of the Royal College of Surgeons, the Provost and Magistrates of Leith, the President of the Merchant Company, and the President of the Chamber of Commerce of Leith.

Turning to the Continent, we find that from Brussels the list of demands already numbers 110 applicants in the Industrial Department, and 117 artists. Two organs are offered, and a large number of other musical instru- ments.

Forty of the best artists of Düsseldorf have given their adhesion, and a large number of the Scandinavian painters, headed by M. Adolph Tidemand. Munich will fur- nish cartoons of the most celebrated artists, and all the leading painters will contribute, including Kaulbach, Schwind, Piloty, Froltz, and Schraudolph.

Great interest is manifested among the industrial and commercial classes of Prussia in regard to the forthcoming International Exhibition of Industry and Fine Arts in Dublin. This is especially true of the manufacturing districts of Rhineland and Westphalia. The Commercial and Industrial Society for Rhineland and Westphalia, whose domicile is in the flourishing Rhenish city of Dusseldorf, at its last general meeting appointed its com- mittee to be the local committee for advancing the objects of the Exhibition in the two provinces in question. In Dusseldorf, too, resides Herr Von Sybel, who has been appointed by the Dublin Committee as its commissary for Prussia. In all the principal papers of Berlin, and, indeed, of Prussia at large, this gentleman has inserted advertise- ments inviting the commercial and manufacturing classes in all parts of this country to become exhibitors. The response on the part of the latter has turned out so far highly satisfactory, and Prussia may be expected to make a very respectable show in the Dublin Exhibition during the coming summer.

STRATFORD INDUSTRIAL EXHIBITION.

On Tuesday, the 27th December, a meeting took place in the buildings of the National Schools belonging to St. John's Church, Stratford, to open an Industrial Exhibition of works of art and manufactures, for the purpose of raising funds for the completion of a Workmen's Hall and Club for the artisans now congregated in the populous parishes of West Ham, Stratford, &c.

This movement has been most warmly taken up and promoted by the inhabitants generally, and the schools on this occasion were filled to overflowing by the ladies and gentry of the neighbourhood. The exhibition of paintings, water-colours, and drawings especially attracted attention, many of them by amateurs, which were contributed for sale in aid of the funds of the proposed Institution. There is also a large collection of objects of natural history, mechanical contrivances, and manufactures. The proceedings commenced at twelve o'clock, by the choir singing the Hallelujah Chorus. The secretary then called upon the Rev. A. J. Ram, the vicar of the mother parish, to open the exhibition, and in doing so expatiated on the benefits of such exhibitions as this, and of the blessings which a hall and club were calculated to confer on the working classes. He congratulated the meeting on the success which had crowned the labours of the Committee (mostly working men), and complimented them upon having been able to collect so large a display of works of industry and art.—Mr. ANTONIO BRADY then addressed the meeting, and in doing so said he felt it a great honour to be associated with this movement, and had lent his choicest pictures and works of art with the greatest pleasure. He could only attribute his being called upon to speak first, to his position as one of the trustees of the schools, and to his taking so great an interest in the cause of education. He felt that this exhibition was education in the highest and truest sense of the word, and it afforded him much satisfaction that the trustees had lent the schools as desired. Mr. Brady then spoke to the working men, and showed the vast difficulties of artisans in earlier times contrasted with the present. He directed attention to the remains of the mammoth on the table, which he had lately procured from a neighbouring brick-field, being part of one of very many of those ancient inhabitants of Stratford whose race was now extinct upon the earth. He then pointed to the magnificent collection of flint and other stone tools in the adjoining cases, some of which had been used by man, the contemporary of the mammoth and other extinct mammalia which formerly roamed in these districts in countless numbers, the quantities of mammalian remains found in this neighbourhood being almost fabulous. The flint tools consisted of axes and tomahawks from Amiens and Abbeville in France, and hammers, chisels, saws, knives, spear-heads, daggers, sling-stones, &c., from the lower peat formations in Denmark. Mr. Brady shortly described the age of those instruments by the flora of the then existing country. He stated that the Danish antiquaries and naturalists, Professors Nilsson, Forchhammer, Thomsen, Worsaae, and others, have succeeded in establishing a chronological succession of periods, which they have called the ages of stone, of bronze, and of iron, named from the materials which have each in their turn served for the fabrication of implements, specimens of each of which Mr. Brady had lately obtained in Scandinavia, and had placed on the tables. The age of stone in Denmark was represented by the period when the Scotch fir flourished, and is the principal vegetation found with the flint and other stone tools at the bottom of the peat formations. The bronze age coincided with the time when the Scotch fir had given place to forests of oak, bronze tools, swords, spears, shields, &c., being found in the middle peat associated with acorns and stems of the oak. This was succeeded by the dawn of the present period, and is represented by iron tools, much of the same character, found on the top growth of the peat, associated

with forests of birch and beech, the oak and the Scotch fir being now only found in these parts in a state of cultivation. It would seem, at first sight, strange that primitive man should first have fashioned his tools of a compound metal—bronze; but as iron is mostly only found in the state of an oxide, and the other metals of which bronze is compounded often occur in a metallic state, it is only natural that man should have first learned the use of them, the chemical knowledge necessary for the reduction of iron showing an immense stride in civilisation and the arts. The tools make it apparent that weapons of defence and offence were the first necessities of our race, "when wild in woods the noble savage ran." He used flint knives to skin his animals for clothing and food, and made wedges and axes to fashion wood for his hut, or to hollow out trees for his tiny bark, wherein he pursued good old Isaac's gentle art with spear and arrow-heads wherewith to kill his game; and, for truth's sake be it added, with daggers and other offensive weapons, it is feared, for a less holy purpose. We thus trace, by means of these antiquities, the progress of man by slow degrees, until after the lapse of countless ages (how many is known only to Him to whom a thousand years are as one day,) we are able to compare these ancient tools, which date from the era when the mammoth and the rhinoceros walked this earth, with the elaborate and exquisitely-finished machine tools of the present day. We thus see how the flint arrow-head has given place to the Minie rifle or the Armstrong gun; we can point to the iron horse of the railway, which never tires; to the steam-engine printing-press; and the electric telegraph, which latter is doubtless the greatest achievement of man in subduing the elements to his service. We span the earth as it were with a girdle, and catch a flash of lightning wherewith to convey our thoughts through the sea to the uttermost parts of the earth. Yet, to show that civilisation is not complete, and that man still lives in remote islands without the use of improved materials, Mr. Brady pointed to a fish-hook made of wood, and to a tomahawk with a stone axe for its cutting edge, which his brother lately brought from the Louisiade Archipelago, where metals are still unknown. Thus, interchange of thought and comparison of what one man can do with the work of another is the great means of progress and the great advantage of such exhibitions as these. Lord Bacon truly says, "Knowledge is power, and is the accumulated wisdom and experience of all men and all ages." Then let us profit by such educational exhibitions as these. After some further remarks of a general nature, the speaker paid a warm tribute to the exertions of the Committee by whom the rooms had been so beautifully decorated and arranged; and especially, he thought, that a vote of thanks was due to Mr. and Mrs. Warner and family—the first idea of this Hall and Club, now on the point of being realised, being due to Mrs. Warner.

The meeting was then addressed by Mr. BASSETT, an artisan; Mr. C. TANNER; and Mr. JOHNSON, a working man.

The National Anthem was effectively sung by the choir. The Rev. Mr. KEOGH then moved a vote of thanks to the Vicar for presiding, which was seconded and carried unanimously.

The Rev. A. J. RAM briefly responded, and formally declared the exhibition open.

ON PERFUMES, FLOWER FARMING, AND THE METHODS OF OBTAINING THE ODOURS OF PLANTS.

By SEPTIMUS PIESSE, PH.D., F.C.S.

The following lecture has been delivered before the Royal Horticultural Society, and illustrated with living plants:—

Perfumes that are derived from plants, may be, for the

of description, conveniently divided into three

I. are the most ancient, and have been in use from the earliest period of which there is record. They consist of the various odoriferous gum-resins, which are naturally from the trees which yield them; and among the produce, the plants are often purposely cultivated. The most important are benzoin, olibanum, and camphor. No less than 5,000 cwt. of these are annually imported into Britain. Gum-resins are the chief ingredients in incense and in pastilles.

Here are specimens of benzoin, myrrh, frankincense, and numerous others.

These odoriferous bodies are principally consumed in religious ceremonies, and from the early custom of burning incense upon the holy altar, our word perfume, or *fumus* (by smoke), has been derived.

Here will find displayed here some fine specimens of contrivances in the contrivances for burning incense, and the bodies for fumigation.

They may include in this class all those parts of plants which are fragrant, such as the long seed-pod of the vanilla; the bean of the *Dipteris odorata*, or tonquin which our grandfathers carried in their snuff boxes; the root of the *Iris florentina*, or orris root, about 25 tons of which are consumed every year by Britannia at her palaces; the rhizome of an Indian grass, known as vitiver; the fragrant woods, such as the santal, and the rosewood or violet wood of Australia; odoriferous seeds, as nutmeg and nutmeg; in fact, our first division includes every vegetable substance which has a pleasing fragrance, such as the dried flowers. Perfumers grind these several to powder, then mix them in various proportions; and the salts are, the various sachet powders in such use, i.e., examples of which are now given.

II. are those perfumes which are procured by distillation. This is the first step to separate the odorous principle from the material which contains it. As soon as the Greeks and the Romans learned the use of the still, they had an invention imported by them from Egypt, which they adapted it to the separation of the odorous principle from the numerous fragrance-bearing plants which are indigenous to Greece and Italy. An essential oil, thus procured from orange-flowers bears in this day the name of Neroli, supposed to be derived after the Emperor Nero. Long before that time, however, fragrant waters were in use in Arabia, as we learn who read the Arabian Nights. Odorous plants contain the fragrant principle in minute glands or sacs; these are found sometimes in the rind of the lemon and orange; in others, it is in the leaves, sage, mint, and thyme; in wood, as rosewood and sandal wood; in the bark, as cassia and cinnamon; in seeds, as caraway and nutmeg. These glands or bags may be plainly seen in a thin cut stratum of the peel, from which the otto may be easily pressed out on paper; so also in a bay leaf, if it be held up to the light, all the oil-cells may be seen like specks.

These fragrant-bearing substances yield by distillation an oil peculiar to each; thus is procured otto of patchouly from the leaves of the patchouly plant, *Pogostemon*, a native of Burmah; otto of caraway, from the caraway seed; otto of geranium, from the leaves of *Geranium rosea*; otto of lemon, from lemon peel; and a hundred others of more infinite variety.

These various ottos are very slightly soluble in water, and in the process of distillation the water which remains over is always fragrant. Thus elder water, rose water, orange water, dill water, are, as it were, the residue of the distillation after obtaining the several ottos. Some of these fragrant waters will be found here. We will see so much of the plant with water as is just sufficient to render the water fragrant without any otto floating in it. This is the practice when the water alone is the subject of distillation. The process of distillation is simple; the fragrant part of the plant is put into

the still and covered with water; and when the water is made to boil, the ottos rise along with the steam, are condensed with it in the pipe, and remain floating on the water, from which they are easily separated by decanting. Models of the still are here shown, and on the wall we have a sectional diagram of this wonderful instrument. In this way 100 pounds of orange, lemon, or bergamot fruit peel will yield about 10 ounces of the fragrant otto; 100 pounds of cedar wood will give about 15 ounces of otto of cedar; 100 pounds of nutmeg will yield 60 to 70 ounces of otto of nutmeg; 100 pounds of geranium leaves will yield 2 ounces of otto. A simple mode of procuring the ottos from orange, lemon, and bergamot is practised in Italy. The fruit is rasped, the pulp produced is then pressed. The odours of the fruit thus procured are much finer than those obtained by distillation.

Every fragrant substance varies in yield of essential oil. The variety of ottos are as numerous as fragrant plants; but there is a certain relationship among odours as among tints. The lemon-like odours are the most numerous, such as verbena, lemon, bergamot, orange, citron, citronella; then the almond-like odours, such as heliotrope, vanilla, violet; then spice odours, cloves, cinnamon, cassia. The whole may be classified into twelve well-defined groups. All these ottos are very soluble in alcohol, in fat, butter, and fixed oils. They also mix with soap, snuff, starch, sugar, chalk, and other bodies, to which they impart their fragrance. And it is thus that we are enabled to transfer the odorous principle from the plant that produces it to an inodorous body, wanting fragrance alone to make it of commercial value.

The principal consumption of the various fragrant ottos is for scenting soap. Windsor soap, almond soap, rose soap, and a great variety of others, consist of various soaps made of oil and tallow, perfumed while in a melted state with the several named ottos or mixtures of them.

Though snuff is by no means so popular an article in the reign of Victoria as it was in Anne's time, yet the increased population, and still more increased exports to colonies, cause a much larger production of scented snuff now than was the case fifty years ago; snuff perfumed with bergamot is especially in demand in the fur countries of Northern Canada. There is a large consumption of fragrant essential oils in the manufacture of toilet powders. Under the various names of rose powder, violet powder, &c., a mixture of starch and orris root powdered, differently scented, is in general demand for drying the skin after the bath.

More than 200,000 pounds weight of various ottos were imported into Britain in 1860, and valued at over £180,000; to this must be added at least one-third as much again distilled in England. Of the imported articles enumerated, oils of lemon and bergamot, from the Two Sicilies, reached 128,809 pounds, valued at £57,054.

Samples of various ottos are to be seen here, and so far as is practicable you will find also the living plant, or dried specimen, from which the odour is derived.

We now pass to Class 3.—These are the perfumes proper, such as are used for perfuming handkerchiefs. Contrary to the general belief, nearly all the perfumes derived from flowers are not made by distillation, but by the processes of *enfleurage* or inflowering, and by maceration or infusion.

The odours of flowers do not, as a general rule, exist in them as a store or in a gland, but they are developed as an exhalation. While the flower breathes it yields its fragrance; but kill the flower, and fragrance ceases. It has not been ascertained when the discovery was made of condensing, as it were, the breath of the flower during its life; what we know now is, that if a living flower be placed near to butter, grease, animal fat, or oil, these bodies absorb the odour given off by the blossom, and in turn themselves become fragrant. If we spread fresh unsalted butter upon the inside of two dessert-plates, and then fill one of the plates with gathered fragrant blossoms

of clematis, covering them over with the second greased plate, we shall find that after twenty-four hours the grease has become fragrant. The blossoms, though separated from the parent stem, do not die for some time, but live and exhale odour; which is absorbed by the fat. To remove the odour from the fat, the fat must be scraped off the plates and put into alcohol; the odour then leaves the grease and enters into the spirit, which thus becomes "scent," and the grease again becomes odourless.

The flower farmers of the Var follow precisely this method on a very large scale, with but a little practical variation, with the following flowers—rose, orange, acacia, violet, jasmine, tuberose, and jonquil. The process is termed, as said before, *enfleurage* or inflowering. In the valley of the Var, there are acres of jasmine, of tuberose, of violets, and the other flowers named; in due season the air is laden with fragrance—the flower harvest is at hand. Women and children gather the blossoms, which they place in little panniers, like fishermen's baskets, hung over the shoulders. They are then carried to the laboratory of flowers and weighed. In the laboratory the harvest of flowers has been anticipated. During the previous winter great quantities of grease, lard, and beef-suet have been collected, melted, washed, and clarified. The great success of this process depends on the absolute purity of the grease employed, and no pains are spared to this end. In each laboratory there are several thousand *châsses* (sashes), or framed glasses, upon which the grease to be scented is spread, and upon this grease the blossoms are sprinkled or laid. The *châsse en verre* is, in fact, a frame with a glass in it as near as possible like a window-

sash, only that the frame is two inches thicker, so that when one *châsse* is placed on another, there is a space of four inches between every two glasses, thus allowing room for blossoms. Every *châsse*, or sash, is about two feet long by eighteen inches broad, as here seen. The flower blossoms are changed every day, or every other day, as is convenient in regard to the general work of the laboratory or flowering of the plants. The same grease, however, remains in the *châsse* so long as the particular plant being used yields blossoms. Each time the fresh flowers are put on, the grease is "worked"—that is serrated with a knife—so as to offer a fresh surface of grease to absorb odour. The grease being inflored in this way for three weeks or more—in fact, so long as the plants produce blossoms—is at last scraped off the *châsse*, melted, strained, and poured into tin canisters, and is now fit for exportation. We have here specimens of fat thus inflored.

In every moderate-sized flower laboratory there are employed from two to three thousand sashes.

Fat or oil is perfumed with these same flowers by the process of maceration; that is, infusion of the flowers in oil or melted fat. For this end, purified fat is melted in a *bain marie*, or warm bath, and the fresh blossoms are infused in it for several hours. Fresh flowers being procured, the spent blossoms are strained away, and new flowers added repeatedly, so long as they can be procured. The *bain marie* is used in order to prevent the grease becoming too hot from exposure to the naked fire; so long as the grease is fluid, it is warm enough. Oil does not require to be warmed, but improved results are obtained when it is slightly heated.

A represents a pile of glass sashes.

B represents a sash with lard and flowers upon it.

C represents a wire sash for the enfleurage of oil upon a cotton fabric.

We have upon the wall here a sketch showing the water-bath for melting the fat or warming the oil.

Jasmine and tuberose produce best perfumed grease by enfleurage, but rose, orange, and acacia give more satisfactory products by maceration; while violet and jonquil grease is best obtained by the joint processes—enfleurage followed by maceration.

We have here a *châsse en fer*, this is for the enfleurage of oil. In the place of glass, the space is filled with a wire net; on which is laid a *molleton*, or thick cotton fabric—mole-skin, soaked with oil; on this the flowers are

laid, just as with solid grease. In due time—that is, after repeated changing the flowers—the oil becomes fragrant, and it is then pressed out of the mole-skin cloth. Oil of jasmine, tuberose, &c., are prepared in this way.

There is certainly something inscrutable to an Englishman about olive oil; he only knows it as it were with a lamp-like odour; but the olive oil that is pressed from the native fruit of the Valley of Cannes, has less taste and less odour than the finest Aylesbury fresh butter. Such oil therefore is admirably adapted for inflored, for it is obvious that bodies which have no odour of their

own, are more easily perfumed than those in which the original odour has to be overcome before they smell of the substance with which they are odorated.

In order to obtain the perfume of these flowers in the form used for scenting handkerchiefs, we have to infuse the scented fat or oil, made by any of the above methods, in strong alcohol.

In extracting the odour from solid fat, it has to be chopped up fine, as suet is chopped, or melted, and then put into the spirit, and left to infuse for about a month. In the case of scented oil it has to be repeatedly agitated with the spirit. The result is that the spirit extracts all the odour from the fatty body, becoming itself "perfume," while the grease again becomes odourless; thus is procured the essence of jasmine, essence of orange flowers, essence of violets, and others already named, rose, tuberose, acacia, and jonquil.

It is remarkable that these flowers yield perfumes which, either separate or mixed in various proportions, are the types of nearly all flower odours; thus, when jasmine and orange flowers are blended, the scent produced is like sweet-pea; when jasmine and tuberose are mixed, the perfume is that of the hyacinth. We will practically exemplify this; thus all the various bouquets and nose-gays, such as "frangipanni," "white roses," "sweet daphne," are made upon this principle.

The commercial importance of this branch of perfumes may be indicated by the quantity of flowers annually grown in the district of Cannes. Flower harvest: Orange blossoms, 1,475,000 lbs.; roses, 630,000 lbs.; jasmine, 100,000 lbs.; violets, 75,000 lbs.; acacia, 45,000 lbs.; geranium, 30,000 lbs.; tuberose, 24,000 lbs.; jonquil, 5,000 lbs. The quantity produced at Nice I have been unable to ascertain; with violets and orange there are more, but with cassie less, than here stated.

In growing flowers for perfumery the item of wages is, of course, important. In the Valley of the Var, the summer wages are 2s. 4d. a day for those men who do the heavy work of the fields, and 1s. 1d. a day for the women who attend to the flowers. In winter, which is but of short duration, the wages are 2s. a day for men, and 10d. for women.

Nothing can be simpler or more primitive than the farming operations. Roses for example. The field is first scantily manured, especially with the refuse matter left after the distillation of various plants; it is then ploughed with oxen at the yoke. Young plants of roses, procured from layers, in the usual way, by tonguing and layering at a joint, are then planted, and Nature does the rest. The cabbage Provence rose is the kind cultivated. In the second year a considerable quantity of flowers appear, but it is not until the fourth year that they are fully developed. A plantation of roses well tended will last from six to eight years; but for this the land must be well drained. It requires about 7,000 rose plants to cover an acre, and this acre will produce, in an average season, 5,000 pounds' weight of roses of the value of 1d. to 1½d. per pound, yielding, say £30 an acre.

For cassie (*Acacia farnesiana*) the land is prepared in a similar way. The young plants are raised from seed, which is sown in beds. The best plants are left, the doubtful ones removed. In the third year they have generally a height of two or three feet, and are then planted out in fields, each tree requiring about twelve feet square. The blossoms of the cassie are successive, some being ready for plucking while the others are scarcely formed. This is immensely useful to the farmer, one lot of blossoms being gathered and passed through the laboratory before it is time to gather the others. After the third year the tree produces flowers, growing at the same time till they attain maturity, when they reach a height of ten or twelve feet, with branches six feet long, and a stem as thick as a man's wrist. Each full grown tree will produce about two pounds' weight of flowers, value from 3d. to 4d. per pound, say £30 to £40 per acre.

The jasmine is cultivated by alips of the wild jasmine (that which is seen in our English gardens) grafted, at the end of two years, with the Spanish jasmine (*Jasminum grandiflorum*). This produces a blossom the size of a shilling, of intense fragrance. It requires about 8,000 plants to stock an acre; and they are not in full bearing till the second year after grafting; but when mature, every thousand plants yield about sixty pounds' weight of flowers annually. They are planted in rows, horizontal poles being thrust between them for support, the branches are woven in and out, somewhat as the raspberry canes are arranged by the Chiswick gardeners. Every August—the jasmine season—the fields are alive with women, old and young, and children, each having a little basket at her side suspended by a strap across her shoulders, both hands actively engaged in picking the flowers, and filling the baskets. As each basket is filled it is conveyed to the shaded laboratory and there weighed. An acre of land will yield about 500 pounds' weight of jasmine blossoms. The value of the blossoms varies from 1s. to 1s. 6d. per pound.

The tuberose needs more care than any other flower of the farm. It is the most difficult to rear, but the best worth rearing. A good plantation on a good soil will last for seven or eight years. It is a bulbous plant, and propagates as they do; it throws out a stem like a hyacinth, covered with fleshy flowers. And oh! what a fragrance breathes from it! what a bouquet, snatching perfumes from every flower with a superb eclecticism!

"The Tuberose, with her silv'ry light,
That in the garden of Malay
Is called the mistress of the night,
So like a bride, scented and bright,
She comes out when the sun's away."

Orange-trees are raised from seeds; at the third year they are grafted, either with the sweet Portugal or bitter Bigaradier. A tree requires fifteen years to reach maturity, but will produce both flowers and fruit in four or five years. When in full vigour, each tree yields an average of twenty-five pounds' weight of blossoms annually. Many plantations of orange-trees at Nice are more than one hundred years old. At Fontainebleau there are now to be seen orange-trees planted by an ancestor of mine two hundred years ago. At Nice there is a public market for orange-blossoms during the season; the bitter orange-flowers fetch 3d. per lb., the sweet about 2d.

The orange-tree yields not only the exquisite odour of the flowers by the enfleurage process, of which there are several examples here, but also the otto from the flowers by distillation; there is also quite a different smelling otto from the epidermis of the fruit, as here shown, and also a very fine otto from the leaves.

The market season for orange-flowers at Nice lasts for more than a month, as an average, and during that time there are sold about fifteen to eighteen tons of flowers daily! a ton of flowers will yield more than a kilogramme of otto, say forty ounces, worth £20 sterling; and the residuary water, highly saturated with odour, is worth another £10 note.

With us the violet grows anywhere, and almost anywhere; but the terrible sun of Nice, during July and August, is but ill borne by the violet. Consequently, on the farms they are planted under the green shade of the orange and lemon trees, or close to walls and houses. The method of propagation is division of the roots. They are planted so as to grow in tufts or clusters about a foot apart all round; and this space enables the growers to gather the flowers without treading on them. A surface of land, equalling an acre of planting, yields one hundred and eighty to two hundred pounds' weight of flowers, valued as an average at two francs the pound. Violets may always be looked upon as an extra crop, growing as they do under the orange and lemon trees. The kind grown is the double Parma. About twenty-

five tons weight of violet blossoms are produced annually at Nice.

Oak-leaf or rose-leaf geraniums are grown for the sake of the rose-like odour extracted by distillation from their leaves. A ton of leaves will yield about a kilogramme, or rather less, of otto. The geranium is propagated by cuttings made in September, which are planted out in the spring.

Rosemary, lavender and thyme are also grown to a vast extent. One can hardly say "cultivated," since they grow like the broom and heath on the wild wolds of Yorkshire. Any quantity may be found on the high regions of the Maritime Alps. Those persons who seek for the ottos of these plants carry the distilling apparatus up the hills upon the backs of mules, while they encamp themselves in tents near to some snow stream.

England has always been famous for the production of lavender, and farms of it exist at Carshalton and Mitcham, in Surrey; also at Hitchin, in Hertfordshire. It requires about 3,600 plants to an acre, and when the plant is in full bearing we can procure from this quantity about six to seven quarts of otto, which, at the present price of 54s. per lb., a good average price of ten years, yield £32 per acre.

Although the mode of obtaining the odours from flowers by enffeurage and maceration, has certainly been in practice for two centuries in the valley of the Var, in the south of France, it is only by my publications that the method has been made generally known in England.

The works published relating to perfumery are very few. In France, where this commerce has risen annually to the value of £3,000,000 sterling, there are no published accounts or statistics by a native author, relating to flower farming. My own little book, "The Art of Perfumery," has recently been translated into French, by Dr. Baveil, of Paris, and is published by Ballière. No cyclopædia, which is more than ten years old, makes even mention of the inflooding process, as a source of entrapping the exquisite odour of flowers, nor do any of the multitude of books relating to economic gardening, notice this fact.

No wonder then that gardeners and horticulturists generally, are unacquainted with this simple source of wealth, and if I interpret right the object of the Council of this Society now in bringing the subject of the odours of plants before the fellows, it is that young gardeners, aspiring to emigrate to some of the warm British Colonies, may eventually lay there the foundation of a flower farm and perfume laboratory, such as can only now be seen on the banks of the Var.

Fine Arts.

ART IN IRELAND.—The following letters have been addressed to the editor of the *Times*, in answer to a leader, in which some remarks disparaging to Irish Art were made:—

"Sir,—A word or two, if you please, in answer to some of your assertions that "art is not in Irish people," and that "in Ireland, nature and art do not get up their usual friendship" and to your "doubts of the possibility of an Irish School of Art." Ecclesiastes tells us whatever has been shall be; and it is the fact that in some remote age there was an Irish School of Art, one as marked as the Etruscan, of the truth of which a visit to the Irish academy will satisfy you. You will find there a collection of ornament in gold which in quantity rivals that at Naples or Rome, and in artistic quality is not inferior to the works of the Greeks. The book of Kells and other illuminated MSS. on Irish art are as peculiar and fine of their kind as any MSS. of any age or country. For two centuries architecture certainly has been no better in Ireland than in England; and if we find Dublin "overdone with huge porticoes, towering domes," and the like, we may recollect that within forty years the architectural

genius of England could do nothing more original than the British Museum and the General Post Office, and crib from the temple of Theseus innumerable stucco versions of porticoes to front Unitarian chapels. Art not in the Irish people! Last year we lost Mulready, whose pictures united qualities found but separately in Van Eyck, Beato Angelico, and Ostade, with a power of correct drawing equal to that found in Greek gems—and Mulready was born at Ennis. What living artist, in France or Germany, or modern Italy, has painted a more noble wall decoration than the Battle of Waterloo in the Houses of Parliament? and Daniel Maclise came from Cork, and first copied those "plaster busts in the Cork School of Art" which you seem to hold in some contempt. I venture to think that modern art has produced no finer work than this water-glass picture, a process which the artist was the first to introduce into this country. And is not Foley, too, an Irishman, at the head of British sculptors? and may not the "Eve" of Mac Dowell, the sculptor, an Irishman, challenge most modern works in France and Italy for excellence? Allow me also to tell you that there is "such a thing as a National Gallery in Dublin," the best lighted picture gallery that has been built, where a man can walk in almost when he pleases, even on a Sunday afternoon, as Mr. Sheepshanks wished should be done at Kensington. And it is not true that Schools of Art "do not encourage attempts to draw from life and nature." The copy of their programmes which I enclose, show the contrary. And I would venture to ask you to improve your acquaintance with Schools of Art, which you say is not extensive. I am not an Irishman, but I hope you will allow me this opportunity of raising for a moment a shillalah in defence of art in Ireland.—FELIX SUMMERLY.

Sir,—In a leading article in your journal of yesterday in reference to the recent distribution of prizes to the students in the Government Schools of Design at the Royal Dublin Society, the following paragraph occurs:—"There is no such thing as a National Gallery in Dublin. There is no collection of pictures and sculpture, or other works of art that a man can walk into any hour that he pleases, or even once or twice a week." I am happy to inform you that there is a National Gallery in Dublin; that it includes paintings and sculpture in its collection; that it is open gratuitously to the public on all days of the week, with the exception of Fridays and Saturdays, which are reserved for artists and students, but on which days the public also are admitted at a small charge, and that it is the first institution of the kind in the three kingdoms which has opened its doors for the benefit of the working-classes on Sundays after the hours of Divine service. The gallery was opened on the 1st of February of this year, and the recorded number of visitors up to the present exceeds 167,000, although it was completely closed during the month of October. I send you a catalogue, in the prefatory part of which you will find a brief account of the origin and establishment of the institution; and will perceive that for its collections, however inadequate to public requirements, it is up to the present mainly indebted to private liberality. It is not in my province to comment on the tone and bearing of the article in which so strange an unacquaintance is manifested with the existence of a public institution, the subject of frequent Parliamentary grants; my simple duty is to request that you will, by the publication of this letter, disabuse your readers of the error of supposing there is no National Gallery in Dublin.—GEORGE F. MULVANY, Director.

Merrion-square West, Dublin, Dec. 29.

Manufactures.

THE SCOTCH IRON TRADE.—According to the authenticated returns of the ironmasters, the production of pig iron in 1864 has attained the amount of 1,160,000 tons,

which, at the average price of this year for mixed numbers, reaches the sum of £3,320,000. There have been in blast throughout the year 134 furnaces, giving employment to about 50,000 men. The shipments—foreign and coastwise—and local consumption have sprung up to the grand total of 1,156,000 tons. The stock of pig iron in Scotland, as ascertained by the committee appointed by the iron trade, is now 760,000 tons, thus showing a trifling increase of 4,000 tons. In 1864 the price of pig iron has fluctuated from 67s. to 49s. 8d., giving an average of 57s. 3d. per ton. The demand for malleable iron this year is without a parallel in the history of that material. It is computed that 210,000 tons of pig iron have been used in producing 163,500 tons of bar, sheet, plate, and angle iron, during the last twelve months, whilst our foundries have consumed 270,000 tons.

THE COTTON TRADE.—Messrs. Smith, Edwards, and Co., of Liverpool, report as follows in their Annual Cotton Circular:—The experience of the past year has rather damped the sanguine hopes of those who expected that the vacuum created by this American war would be soon filled up. The opinion was entertained in Lancashire twelve months ago, with the force of a conviction, that 1865 would witness practically the termination of the great cotton crisis, and that, too, irrespective of aid from America. These sanguine auguries have not been fulfilled. The difficulty of replacing a vast cotton field like that of the Southern States is now more fully recognised, and we enter the year 1865 with more sober anticipations than prevailed at the beginning of the last one. Our chief reliance since the American war commenced has been upon the expansion of cotton cultivation in India, but year after year that country has disappointed us, and now, in the fourth year of the war, we are promised no more than in the first. The export of cotton from Bombay for the years 1861, 1862, 1863, and 1864, has scarcely varied from a million of bales, and the general expectation in Bombay is that it will not exceed that amount in 1865. The reports of the growing crop are not favourable; the rains were deficient, and the plant in many places is not looking well; neither was there any increase of planting this season. The scarcity and dearth of food were excessive through all the west of India, and the ryots dared not extend the cultivation for fear of bringing on a famine. From the north-west Provinces, where the Bengal cotton is grown, a large increase of planting is reported, but the crops are said to be deficient. From the South of India some increase is expected. Looking broadly at the case, it may be hoped that India will give a small increase next year, the more so as a large part of the old crop at Bombay has been held back in consequence of the late panic, and will be shipped freely in the early months of the year. Perhaps an increase of 100,000 or 200,000 bales may be received from India this year, but even that appears very doubtful. From China there has been a steady increase of supply since the trade commenced. The import for 1864 sums up to the large total of 399,000 bales, equal in weight (supposing the bales to average a little under two piculs) to nearly 250,000 Surat, or 200,000 American. Since the present season opened the shipments from China are nearly double those of last year, say 200,000 piculs against 106,000. So it is fair to expect a large increase for the whole year, though hardly in the same ratio as this. From Egypt the accounts are most encouraging; cotton culture in that fertile country makes rapid strides from year to year, and it is generally thought that this crop will exceed the last by 25 per cent.; some say considerably more. We have received from Egypt 257,000 bales this year; it is not unlikely we may get 320,000 bales, or even more, next year. From Brazil a large increase is also expected, perhaps 50,000 bales; but, on the other hand, the prospects of supply from America are not so good. The blockade of the Southern ports is becoming more rigid. At Nassau, the chief depot for blockade runners from the Atlantic coast, there is a suspension of

business, and the vessels are leaving for other employment. From Texas there may be a fair supply, but the aggregate 'leakage' from the Cotton States is expected to be less in 1865 than in 1861. From Turkey the accounts of the crops are very unpromising; though a much larger area was planted the crops have failed, and little increase over last year is expected. If these views prove correct, an increase of 200,000 to 400,000 bales may be expected in 1865 over the past year; the import may range from 2,800,000 to 3,000,000 bales, against 2,587,000 bales for 1864, 1,932,000 bales for 1863, and 1,445,000 bales for 1862—the year of smallest supply. The home consumption the past year has taken off 1,606,000 bales, and the export 732,000 bales, being together 2,438,000 bales less than the import, and this amount has gone to increase our stocks. The problem is, whether the trade and export will take off half a million bales more in 1865 at the present scale of prices; otherwise there is likely to be another considerable addition to stock at the close of 1865. That the loss of profit to Lancashire in the last few years has been enormous can be seen at a glance from the small margin that now exists between the aggregate value of the raw material consumed and the manufactured article produced, as compared with former years. Taking the Board of Trade returns of the export of cotton goods and yarn for the last five years, and adding to them an estimate of the amount consumed at home, which we will take as one-third the exports, we obtain a rough approximation to the whole value of the cotton manufactures of Great Britain. If we deduct from this the price paid by our spinners for the raw material consumed, we obtain the amount of profit which the internal industry of the country reaps from the trade. In 1860 a sum of forty millions was distributed among the industrious population of Lancashire, engaged in the cotton trade or the branches dependent upon it. During the last three years this amount has declined to about one-half. Of course there are many modifying circumstances which might be mentioned, such as the profit made upon old stocks held when the war commenced. But again it must be remembered that the exports of 1861 and 1862 were greatly swollen by the shipments of these stocks, and represent more than the real production for these years. Taking all into account, and making allowance for 1860 being a year of remarkable prosperity, it seems fair to assume that the manufacturing industry of Lancashire has suffered to the extent of fifteen millions per annum or more for the last four years, in consequence of the stoppage of the cotton trade with the Southern States, and it is evident that if this exhausting drain upon its capital continues for another year or two, serious consequences must follow in the shape of commercial embarrassment and want of credit.

Colonies.

NEW ZEALAND FISH.—It is well worth the while of the Provincial Council to consider whether it is not necessary to enact some measure for regulating the fisheries of this province (Otago). It is a singular anomaly, that whilst, on the one hand, money is voted for the introduction of new varieties of fish, on the other hand the most wanton destruction of valuable native kind is being tacitly permitted. We might refer to one species of fish alone which is rapidly becoming scarce in this harbour, viz., flounders. The flounder, when in good condition, is a really excellent and valuable fish, but it is rarely now that one can get a full-grown fish; instead of which the fishermen send to market a number of little fry, hardly worth the trouble of cooking. The other day some barrels of fish were being landed from the port steamer, and the contents of two of them consisted entirely of very small flounders, little bigger than sardines. If the reckless

capture of fish, in season and out of season, be permitted to continue, there will very soon be nothing but the deep sea varieties left.

THE BOOK OF PERFUMES. By Eugene Rimmel. (*Chapman and Hall.*) This is a curious and interesting work, the origin of which appears to have been the author's labours to instruct and inform the members of the Society of Arts. "Four years ago," observes Mr. Rimmel, "I had to prepare for the Society of Arts a paper on 'The Art of Perfumery, its History and Commercial Development,' and, to qualify myself for the task, I had to devour a huge pile of big books in order to ascertain through what mysterious arts the ancients ministered to the gratification of their olfactory sense, and to the embellishment of the human face divine. Two years later I was called upon to form part of the Jury at the Great Exhibition, and to draw up the official report of the perfumery class. The researches I had to make on the former occasion, and the observations I gathered on the latter, gave me a complete insight into the world of 'sweet smells,' both ancient and modern." Thinking that the notes he had thus collected, combined with the results of his experience as a practical perfumer, and of his rambles in foreign lands, might prove interesting to some, he has given them to the world in this digested form. After devoting a few pages to the physiology of odours in general, he traces the history of perfumes and cosmetics from the earliest times to the present period. He then briefly describes the various modes in use for extracting the aroma from plants and flowers, and concludes with a summary of the various fragrant materials used in the manufacture. A large number of quaint and characteristic illustrations embellish the work, which will possess an interest for many.

Patents.

From Commissioners of Patents Journal, December 30th.

GRANTS OF PROVISIONAL PROTECTION.

Archers, construction of bows used by—3058—J. Norton.
Atmospheric railway breaks and communications—3083—C. Rendall.
Boots and shoes, manufacture of—2041—W. Clark.
Bottles, jars, &c., construction of—3010—E. Bavan and A. Fleming.
Capstans, apparatus for working—3089—G. Elliott.

Carriages, apparatus for retarding and stopping—3066—T. H. Roberts.
Cigars, pipes, &c., materials for the lighting of—2943—R. A. Brooman.
Cigars, snuffs, &c., preparing tobacco for—3070—L. Morgenstern.
Closets and commodos—3121—J. White.
Coal plates, &c., method of scouring—3104—S. Hood.
Comb—3014—R. A. Brooman.
Cooling and freezing, apparatus for—3062—R. A. Brooman.
Cotton, roller gins for ginning or cleaning—3090—E. W. Otway.
Crinolines, dresses, &c., manufacture of—2062—F. Kreus.
Double suction pump—3155—H. Drusean and P. Laidet, sen.
Elastic substances, machinery for pressing—3181—C. G. Wilson.
Electric insulation—3092—C. Hancock and S. W. Silver.
Fibrous materials, machinery for spinning—3163—J. P. y Liag.
Fire-arms, breech-loading—3159—T. A. Grimston.
Fluids, engines for compressing and measuring—3171—J. Ramsbot tom and T. Blackburn.
Gases, &c., regulating the flow of—3030—T. Atkins.
Glass maker's pots, construction of—3082—E. H. Johnson.
Hats, manufacture of—3129—F. Cooke.
Hydraulic presses, &c., mode of working—3173—L. R. Bodmer.
Knives, cleaning and polishing—3106—G. Kent.
Laces, braids, &c., apparatus for making—3161—E. T. Hughes.
Liquids and gases, raising and drawing off—3127—J. G. Tongue.
Liquorice cakes, &c.—3098—W. Wharidall.
Looped fabrics, manufacture of—3123—M. J. Cotton.
Machinery, straps for driving—3126—M. J. Haines.
Mills for grinding corn, &c.—3135—F. Price.
Ornamenting fabrics—3076—R. A. Brooman.
Parchment, preparation of the surface of—3117—S. W. Hooper.
Paving, system of—2974—V. Gache.
Photographic apparatus—3175—J. H. Johnson.
Ploughs—3141—J. A. Hopkins and C. Culpin.
Ralls or trams—3137—Z. Eastman.
Railway brakes, apparatus employed for actuating—3006—W. Clark.
Railway carriages, &c., facilitating the starting of—3064—J. H. Johnson.
Railways, traction on—3060—C. Crockford.
Rosin, purification of—3080—F. G. Mulholland.
Ruffles, frills, &c.—3096—H. Taylor.
Sanatory toilet apparatus—2808—W. E. Gedge.
Sawing machinery—3078—R. Mathers.
Sheets and surfaces for designs—3094—C. Hancock and S. W. Silver.
Ships, compositions for coating—3147—H. F. McKillop.
Solar time-pieces—3088—A. V. Newton.
Steam boilers, &c., injecting tallow into—3056—H. Wilson.
Steam engines—3139—H. Davey.
Stone, &c., preserving and ornamenting—3084—R. A. Brooman.
Thermometers—3086—W. H. Cullingford.
Vessels, &c., lifting shot to the fighting deck of—3148—Sir F. Blackwood.
Walls, pavements, &c., decoration of—3113—W. Clark.
Watches, &c., construction of—3100—J. G. Tongue.
Wire rods and wire, apparatus for rolling—3195—G. Bedson.

INVENTION WITH COMPLETE SPECIFICATION FILED.

Douches and injections, apparatus for administering—3215—W. E. Gedge.

CANTOR LECTURES.

REPRODUCTION OF NATURAL FORMS BY ART
MANUFACTURE." By B. WATERHOUSE HAWKINS,
F.G.S., F.L.S.

Hawkins will resume his Course, on Mon-
days, as follows:—

6TH.—LECTURE III.—On the varieties of artistic
representation of the forms of animal and vegetable life—
representation; conventional ornamental, allego-
rical and symbolic combinations of animal forms.

7TH.—LECTURE IV.—On the fitness of designs,
adaptation to the conditions of the materials in
which they are to be produced. (Demonstrated by metal-
work, sand-moulding, casting, and chasing).

8TH.—LECTURE V.—On Ceramic Manufactures,
the influence of the material on the design and its
production—modern Terra-Cotta, Della Robbia
polychrome, and Parian.

These Lectures are open to Members free of
charge, and a Member has the privilege of
bringing ONE Friend to each Lecture. A
ticket for this purpose has been sent to
each Member.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

8.—"On the Best Mode of Applying Power to
Railways, on the Metropolitan and other Railways
frequent Stations, and in Terminal Stations." By
W. BARLOW, Esq., F.R.S.

9.—"On the Best Mode of Protecting London
from Ravages of Fire." By CHAS. F. T. YOUNG, Esq.,

10.—"On London Sewage, from the Agricultural
View." By J. CHALMERS MORTON, Esq.

TECHNICAL TRAINING OF ARTIZANS.

The following letter has been addressed to
the Chairman of the Council by Mr. Twining,
one of the Vice-Presidents of the Society:—

SIR,—As it is partly owing to the encouragement
which yourself, as well as Mr. Chester and others of my
colleagues, have given me, that I have been induced to
pursue further the subject of the Technical Training of
Artizans, I feel that I need scarcely apologise for sub-
mitting to you a brief report of the progress which I
have made.

The desirableness of providing for our artisans facilities
for the perfecting and testing of their technical knowledge
and efficiency equal to those enjoyed by their continental
brethren, is impressively expounded in Mr. Davenport's
very able paper, and he has clearly shown that it is the
province of the Society of Arts to take the lead in a
national movement for that purpose. I feel myself called
upon, whilst expressing my concurrence with these views,
to show that my own objects would perfectly harmonize
with them.

My chief object is for the present to induce and enable
the Society of Arts to make the experiment of holding,
in addition to its Annual General Examinations, Technical
Examinations for testing the abilities of certain classes of
workmen, hereinafter described, and of granting certificates
of competency which may be useful to them, and offer a
desirable guarantee to the public.

The following are among the preparatory steps which
I have taken:—

I have obtained, through the kindness of my con-
tinental friends, a considerable amount of interesting
information, in addition to that already published in
England, concerning the Industrial Institutions and
Trades Regulations of various parts of Europe. The
whole is now in the hands of Mr. Iselin, who had under-
taken to prepare a digest or synopsis, bringing into relief
everything likely to be of useful application in this
country. I regret that its completion is inevitably re-
tarded by Mr. Iselin's engagements in connexion with the
Dublin Exhibition.

It was desirable to ascertain what books and other ma-
terials for technical instruction exist and come sufficiently
within the scope of the proposed Examinations to be of
service as text-books. I have ~~not~~ ^{collected} nearly all the
small handbooks of the kind late years in

England, and, finding that scarcely any would answer our purpose, I have procured from Paris a selection of the best French publications of this description. The whole of the collection, amounting to seventy-eight volumes, is deposited at the Society of Arts. I intend getting one or two suggestive specimens of text-books, specially suited to our requirements, prepared by competent authors. Some of them, of which a sketch is already prepared, will embrace, for the use of several trades in common, those elements of scientific knowledge which several require, whilst others will offer for each trade in particular that technical information which specially appertains to it.

It would be too premature to publish a detailed account of the proposed Examinations, but it may be well to state at once that I do not think of interfering with art-workmen, whose attainments can be sufficiently tested by exhibitions, whilst the subject of their training is already in good hands; nor do I intend including the higher class of foremen of manufactures, or the lower class of factory hands. The first experiment would, indeed, be restricted to a few select handicrafts and technical trades, involving knowledge susceptible of being satisfactorily tested, and the acquisition of which wants encouragement.

The success of our manufacturing industry proves that English workmen possess qualities of mind, and a temperament of body, which peculiarly suit them for discharging regularly and efficiently, under the guidance of intelligent foremen and enterprising manufacturers, a definite task assigned to them in the routine of factory work, and mostly involving neither science, art, nor origination. The case is different with the tradesman or mechanic who is expected to turn a ready hand to the various duties of a complex handicraft, and who must rely on his own knowledge and ingenuity for helping himself or for serving his employer. Here we too frequently find shortcomings as to technical knowledge and practical intelligence, which occasion waste of expenditure, annoyance, and discomfort to the public, whilst they entail unnecessary trouble, and oftentimes injury to health or limb on the artisan himself. This is by no means to be wondered at, considering on the one hand the lax system of technical training which has hitherto generally prevailed, and, on the other hand, the absence, among a large portion of the work payers, of that scientific knowledge which would make them alive to, and impatient of, the ignorance of those whom they employ.

Now, in several parts of the Continent, a system of examinations prevails calculated to secure the public, in a great measure, against inefficiency on the part of the artisans they may have occasion to employ, by maintaining among them definite standards of technical knowledge and manual ability, according to their position as subordinate workmen or masters in trade.

The following is an extract from a letter received from a friend in Germany, well acquainted with the manufacturing and commercial industry of that country:—"I enclose an abstract of the law in Prussia concerning the exercise of trades and handicrafts. . . . It is in full practice, and nobody thinks of abolishing it; indeed, it works admirably, and the public are certain to be served by men who understand their trade. In your country any person can commence a trade, whilst in ours he must first show that he has the necessary capacity and knowledge for its successful exercise."

What I propose to adopt is the principle of examinations as a test for and an incentive to efficiency, but certainly not the regulations which in Germany render them compulsory. The Society of Arts Technical Examinations would, of course, be as voluntary as its Examinations in General Knowledge. They would offer benefits without trammels, and care would be taken that they should not unduly interfere with the usages, or even with the prejudices of industrial trades, whose credit and advantage they would, in fact, serve no less than the interests of the work-employing public. I feel confident that if this plan

should be adopted, the young artisan would see more clearly defined what he *must* know and what he *ought* to know. Facilities for acquiring knowledge would be placed before him, together with a prospect of distinction and well-paid employment if he made good use of them; and technical efficiency, being thus rendered a good marketable commodity, would be sure to prosper in this land of pounds, shillings, and pence.

The class of candidates whom we should have chiefly to deal with would differ widely from those who come up to the Society of Arts General Examinations, as to aptitude for receiving instruction, as to the nature of the instruction which they would require, and, consequently, as to the suitable mode of testing it. I believe that in most cases it would be best to imitate the German system and that of the Pharmaceutical Society of London, and to hold for each trade a minor and major examination. The minor would correspond to the denomination of journeymen, companions, or mates, and the major to the denomination of accomplished workmen or masters in trade. For each of these examinations there should be three classes of certificates, marking—Competency, Ability, and Excellency. If our operations obtained general recognition, journeymen or mates would find hereafter that to make their way in the world they ought to be able to show, at least, a third-class minor certificate, whilst a first class major certificate would secure to any man a high standing in his trade.

A mere glance at the educational condition of our second-class workmen will show that the minor examinations could not be carried on by written papers, and would have to be conducted orally, even if this were not rendered necessary by the nature of the questions to be put to the candidates, frequently involving actual practice at the recognition of articles and adulterations, the display of manual ability, &c. In these matters again we could not do better than follow the Pharmaceutical Society, as also in holding the major examinations partly orally and partly by means of printed forms and written answers.

Lectures and classes would be very useful for the preparation of candidates; but this and other similar points, to which it is unnecessary to advert at present, can best be settled when the measures shall have been determined which the Council may be inclined to adopt in the direction mentioned in Mr. Davenport's valuable memorandum. As regards the financial point of view, I may state my willingness to defray, not only the preparation of the text books required, but also the examination fees for the first experiment.—I remain, &c., T. TWING.

Proceedings of Institutions.

BACUP MECHANICS' INSTITUTION.—On the 3rd January, the 26th Annual Soirée of this Institution was held, when the spacious hall was crowded in every part. After tea, to which about 700 sat down, the Venerable President, Lawrence Heyworth, Esq., opened the proceedings, and took the opportunity to present several books to the society. The secretary's report stated that the finances were in a healthy state, there being a balance in hand of £12 10s. The number of members on the books had averaged 245 per quarter. Ninety volumes had been added to the library, and an increase had taken place in the issue of volumes to the members, the total having been 7,038, or an average of 41 to each member. The increase in attendance at the evening classes has been considerable. In efficiency, as tested by the local Society of Arts, Science and Art, East Lancashire, and Lancashire and Cheshire Union Examinations, the school has made decided progress. A great many prizes and certificates have been obtained by the scholars. It is a source of regret that in some of these examinations the candidates are almost entirely from the younger members of the classes, while elder ones make no attempt to compete in them.

ishment of the Science Classes, in which and Physiology are taught, has been attended with results, and has given a status to the Institution which otherwise could not have obtained. The as evidenced by some excellent songs and music: utinas entertainment; and speeches were made by the gentlemen:—Alexander Mackie, Esq., M.P.; the Rev. J. A. Strenuous, of Glasgow; the Rev. M. Johnson and T. Lawson, of Glasgow; Esq.; Capt. Aitken, the Chairman, and his gentlemen in the neighbourhood.

LIX INTERNATIONAL EXHIBITION.

Official patronage extended to the under-her Majesty has further evinced her interest in the International Exhibition, by consenting to lend collection pictures by the following painters.—Melrose, Stanfield, Roberts, and Thomas. The Committee, presided over by Viscount Powers, these very successful in obtaining the loan of valuable works; and Sir J. J. Coghill, Bart., committee, is coming over to England to select from the collections of noblemen and gentlemen have expressed their disposition to lend works. Indian Colonies, although labouring under difficulties from the short notice given them and the of obtaining legislative grants so soon after London Exhibition, will be very fairly represented by small but interesting collections of produce. The Australian Colonies will have of their wools, wines, fibres, silk, woods, grain, arrowroot, minerals, and objects of ivory, and even some illustrations of fine arts and pictures. India will show a magnificent of raw products and rich manufactures, arranged by Watson, of the India Museum. Ceylon will show the carved stonework, silver filigree, and for which she is so famous, with probably silk and other articles. The North American making some preparations to be represented. the West India islands send furniture, cotton, fibres, objects of natural history, shell work, stone wood, and other walking sticks, which have us into a large and profitable trade, besides these staple products which are the mainstay industry. Lagoa, Sierra Leone, and other West Indies, will make a fine display of native mate work, country cloths, native curiosities, carved and articles of produce. Most of the African and companies have promised their aid in consequence. Other Colonies will contribute produce and objects of various kinds.

THE ART AND OTHER REPRODUCTIVE ART PROCESSES.

By S. T. DAVENPORT, Esq.

antiquity of the art of engraving it is not my do more than allude; it is abundantly evident known to the Egyptians, and used long prior to the Christian period. The art was probably one which the necessity of attaching some distinguishing individual works, or from the custom of recording of the early ages by cutting them in stone, glass of which have been preserved to us. Soft also impressed with the maker's marks, as in ancient bricks and other plastic bodies; and was in the first instance an isolated mark, and not a reproductive art. From a sculptured or al art a refined art grew up, of which, and the by which it attained at an extremely early date, ed gems and seals preserved in our museums

give ample evidence. Engraving on metal was early employed as a means of ornamenting articles of dress; and the coins preserved to us show how the skill of the die-sinker and engraver in metal became the basis of another reproductive art. Engraved metal plates have been found in the coffins of mummies, and are preserved in the British Museum. In India engraving on plates of copper appears to have been practised long prior to the Christian period. It was there customary to ratify grants of land by deeds of transfer actually engraved on copper, and a copy of one such relic, with an English translation, is given by Mr. Wilkins, in the 1st vol. of the "Asiatic Researches," page 123,—an early proof of the commercial use of engraving. To trace the history of engraving on stone and metal to the period when the art of printing was discovered, would only be to repeat an oft-told tale, and tend to prove that the one object which all appear to have had in view has been to facilitate the means of reproducing, at a cheaper rate and by a more ready means, copies of the works of the artist and engraver. It has appeared to me that the present is not an inopportune time for reviewing some of the changes which have been either introduced, or proposed for introduction, during the last half-century, and which have placed us in our present position with reference to the art of engraving, or its substitutes, for illustrative commercial art purposes. With a view, however, of making what I have to say more clear, it is necessary that I should state what were the peculiarities of the art processes in common use prior to the beginning of the present century. The earliest specimens of prints from engravings were those obtained from wood blocks on which the design was cut in relief, but the art of engraving on wood, though greatly improved, continued in an extremely imperfect state till within the last half-century. The perfection to which the art had attained in the year 1803, may be ascertained by a reference to Vol. xxi. of the Transactions of the Society of Arts, in which is printed a specimen showing the great progress which the art had made at that date; and at page 15 of the Preface we find the following:—"It has been frequently asserted that the art of engraving on wood is not, at the present day, equal to what has been done by some of the ancient masters, but when the emblematical performance of young Austin in this line, prefixed to the present list of premiums, is considered as the work of so young an artist, it may probably appear that it cannot be excelled by many artists in Europe of a similar age, and the reward assigned is likely to excite his emulation to progressive improvements in that art." The reward given was the silver medal and ten guineas—and the block was for many years used by the Society as a specimen of the art, and was printed at the head of the Secretary's letter announcing the election of new members. The art was, however, carried to considerable perfection by Bewick, who applied it in the illustration of his "Natural History of Beasts and Birds," and the commercial condition of wood engraving may be seen by a reference to that work. The earliest specimen of a print from a wood block is one known as the St. Christopher, and is dated 1423.

The earliest use of engraved metal plates in England probably dates from the time of the Conquest, but Mr. Strutt states that he has not seen any with a date prior to 1284. They were then used as monumental brasses or tablets, and were executed with the graver, and are assumed to have been produced by ecclesiastics. The same principle which was applicable to the production of monumental brasses, viz., the removal of a portion of the surface of a metal plate by cutting it away, according to any desired design, by means of the graver, was applied by goldsmiths in the production of Niello work. The earliest known print from a metal plate is one which can be seen at the Imperial Library, Paris; it is attributed to Tomaso Fregazzara, the Florentine goldsmith, and bears the date 1463, and is the first known book illustrated in this way.

was printed at Rome. The next step in the improvement of the art of engraving is said to have taken place at the beginning of the sixteenth century, and is attributed to Albert Dürer, to whom is ascribed the invention of the art of etching, or drawing with a metal point or tracer, upon a plate, the surface of which was covered with wax or varnish; and the etching or drawing being afterwards permanently engraved in the metal plate by the action of acid. The process of etching afforded an opportunity of exercising any required amount of freedom of hand in the production of foliage or landscape, and soon led to a combination of the two processes, and was the means by which engraved copper-plates were usually produced at the beginning of the present century. This process is known as line engraving; it is a slow, tedious, and costly means of copying works of art; its peculiarity is, that it affords facility for giving a large amount of drawing and minuteness of detail, at the same time that it admits of the greatest possible gradation of light and shadow, and the most perfect artistic effect. The process of etching was largely used by Rembrandt. The most perfect works executed in the early days of this art are, however, to be found in the portraits and historical subjects, for the reproduction of which it was especially suited, though in later times it was largely and most effectively employed in the copying of architectural, monumental, and landscape art. Copper-plate engravings were printed in England, in "Vesalius's Anatomy," as early as 1545, but the English school of engraving cannot be said to have existed till about the middle of the eighteenth century, at which period efforts were made to advance the interests of artists in this country. It was during the reign of George the Third that the Royal Academy was established, and as art advanced, so with its advancement grew up the use by our artists of the etching point and the graver in a more refined and skilful manner. But the mere reproduction of copies of pictures from engraved plates printed in black inks did not long continue to satisfy the public, and efforts were soon made to print in colours from these engraved plates, but no thoroughly satisfactory results were obtained from line engravings in this direction, and recourse was had to the next process, to which I shall call attention.

Line engravings were executed (as before stated) by cutting away the surface of the copper-plate by means of the graver, which, for this purpose, was made concave in its length, and varied from a square to a thin V-shape in its width, thus enabling either a narrow or a broad line to be cut, while by a slight variation of pressure, or by depressing the hand of the operator, the point of the graver was gradually driven along the metal or freed from the plate altogether.

CHALK OR STIPPLED ENGRAVING, the next process to which I have to refer, was, on the contrary, executed by means of a graver of an arched or convex form, which when applied to the copper-plate could not relieve itself from the surface of the metal, the whole tendency, wherever pressure was applied, being to thrust itself deeper and deeper into the metal, leaving a punctured dot, varying in breadth or delicacy according as the graver itself was more or less square or V-shaped on its face. This mode of puncturing the face of a metal plate was known as "chalk engraving," from the clusters of dots being so arranged as to imitate the granulated effect of lines drawn upon cartridge paper with Italian chalk. This process was especially suited to portraiture, or groups of statuary, owing to the softness of its gradations from light to shadow, and the production of an equal grain over the entire surface of a piece of metal. It was ill-adapted, however, to the production of landscape effects.

The MEZZO-TINTO is a method of engraving, the discovery of which is attributed to Prince Rupert, and it may not be uninteresting to quote the following letter by Dr. Diamond, which was communicated by him to the Society

of Antiquaries in 1838, and to which is appended a catalogue of the earliest known works in mezzotint. The catalogue will be found in vol. xxvii., pages 436 to 409, of the *Archæologia*.

TO SIR HENRY ELLIS, K.H., F.R.S., SECRETARY OF THE SOCIETY OF ANTIQUARIES.

"DEAR SIR,—In the last session I had the honour of laying before the Society of Antiquaries, several remarkable specimens of early mezzotint engraving, which prove beyond doubt that the generally received opinion as to Prince Rupert being the inventor of that style of engraving is erroneous. From the examples then exhibited, it appears that the person to whom the merit of the invention is due, is Louis von Siegen (or L. à Siegen), a lieutenant-colonel in the service of the Landgrave of Hesse Cassel. The works of this amateur artist are of considerable rarity; and it is not improbable that they were merely distributed among his friends and patrons. Baron Heineken, in his 'Idée Générale d'une Collection complète d'Estampes,' printed at Leipsic, in 1771, says decidedly that Siegen was the inventor of mezzotint engraving, and observes that the first specimen which appeared was the portrait of the Princess Amelia, Landgravine of Hesse; he adds, that Prince Rupert learnt the art from Siegen, and that eventually it became public. In the new edition of Granger's Biographical History of England we find some observations on the invention of this style of engraving:—'It should not be forgotten that Sir Christopher Wren is said to have been the inventor of mezzotint; it is certain there is a Blackamoor's head by him in a different manner to that of Prince Rupert; also, Vertue, in a manuscript in my possession, mentions a large head *something like mezzotint*, of the Princess Amelia of Hesse, thus inscribed: 'ad vivum a se primùm depictam, novogue jam sculpturæ modo expressam, dicat consecratque L. à S. anno 1643.' Mr. Wanley says there is one of this lady in Lord Hailey's collection of heads, also one of the Comes of Hesse by the same hand, who was the person who taught Prince Rupert.' Mr. Lodge, in his life of that prince contained in his *Portraits of Illustrious Persons*, after mentioning the prince's contributions to science, and various discoveries, says, 'But the discovery which we find most frequently associated with his name, is of the art of engraving in mezzotint, the first hint of which is said to have occurred to him from observing the effect accidentally produced by a soldier scraping some rust off the barrel of his musquet; his right, however, to the strict reputation of inventor has been somewhat questioned, *but with little probability*.'

"It will be seen by this that Heineken's authority is doubted; but Mr. Strutt, in his 'Biographical Dictionary of Engravers,' although more cautious, is nevertheless in doubt on the subject; for he says, after noticing the story of Prince Rupert's observing the soldier scrape the rust from his musquet:—'If the account, as given by Baron Heineken, be allowed as authentic, and it bears every appearance of being true, especially if such a portrait *really exists*, then the probability of the first story is entirely destroyed. I must leave the reader, however, to decide, having given him all the information I could obtain on the subject.'

"Now, from the extracts given, it is evident that neither Strutt, Bryan, Granger, nor Noble have ever seen the engravings in question; and it is a remarkable fact, that not one of them is to be found in the fine collection of the British Museum. The example I have now the pleasure of exhibiting, is a portrait of the eldest daughter of Charles the First, inscribed: 'AUGUSTA MARIA CAROLÆ: M: B: REG: FILIA. PRINCE: AUR. SPONSA.' and is of great rarity; one other only being known in England, namely, that in the collection of Mrs. Sutherland; which is, however, I am informed, very much injured.

present portrait, as a work of art, is curious combining two distinct styles of engraving; the engraving entirely mezzotinto, and the background in cross-hatched. The likeness is highly interesting in the strong resemblance which it bears to the truly, especially to Charles the Second, and his Frederick Duke of Gloucester. Near the base of the portrait in the right-hand corner are the words, *Pinxit, L. à Siegen inv. [enit] et fecit;* and by observation, that the word *Inventor* is found on the works of Siegen. On the Holy engraved by him after Caracci, and dedicated to Mazarin, is the following remarkable inscription: *Invicentissimo Domino D. Julio Mazarini S. R. E. , &c. Novi hujus Sculpturæ modi primus inventor à Siegen humilissime offert, dicat et consecrat,*

Mr. the compiler of Winckler's Catalogue, tells Theodore Caspar de Fürstenbergh, a Capitulary of Mayence, was an engraver in mezzotinto; that he was contemporary with those of Siegen, and a doubt as to which was the disciple of the other, if Fürstenbergh learnt the art of Siegen, or he his master. But there is no evidence what-arrant this doubt; on the contrary, the portrait seen of Bohemia, which I exhibited in February of the date of 1643, while the earliest known of Fürstenbergh is dated 1656. It is only to add that Rupert's earliest effort in mezzotinto etchings of this Prince are earlier, and one is inscribed *Rup. Pr. 1637*) is of the year 1658. In this, I subjoin a catalogue of the known works in the style of Siegen, Fürstenbergh, and Rupert, as the same have not to my knowledge ever been printed.

I have the honour to remain, Sir Henry,

"Your obedient and humble servant,

"HUGH W. DIAMOND."

L. von Seigen (or L. a Seigen), born 1820.

The Virgin holding the infant Jesus. In front, the head of her, is St. John; and behind, St. Joseph with a book in one hand and a pair of spectacles in the other, after Caracci; with the inscription, "*Eminentissimo Principi Domino D. Julio Mazarini S. R. E. , &c. Novi hujus Sculpturæ modi primus inventor à Siegen humilissime offert, dicat et consecrat*" A.D. 1667. (Height 13½ inches, width 10½ inches, inscription.)

Portrait of the Landgravine of Hesse with this inscription: "*Amelia Elisabetha, D. G. Hassiæ Landgravia, Electorissæ Hanovise Muntzenb. Illustrissimo ac Reverendissimo Pr. & D'no, D'no Wilhelmo VI. D. G. Hassiæ Landgraviæ hanc Serenissimæ Matris et Incomparabilis Rege Regiæ ad vivum à se primùm depictam novoq' sculpturæ modo expressam, dedicat consecratq' L. à Siegen*" A.D. 1667. (Height 17 inches, width 13 inches, inscription.)

This is the portrait spoken of by the Baron Heineken. I was also enabled, through the kindness of Dr. Heineken, to append the copy of a letter addressed by L. von Seigen to his Highness the Landgrave of Hesse-Cassel, which I believe has never before been printed in this country, and appears to substantiate his claim to be really the inventor of the mezzotinto art.

HIGHNESS THE LANDGRAVE OF HESSE CASSEL.

Your most high-born Prince—Most gracious Lord,—In the manner as my humble devotion, more than any other consideration of reward, has brought me to your service; though these services, however agreed to by your grace, have been rather derogated by some persons, I have not relented in devoting to your grace my labour, and my time, in proof of which I humbly do present the present print to your grace.

"This is the copper print, most gracious Prince and Lord, which some time ago I mentioned to you to have executed, to your grace's mother's laudable commemoration, with a view to bring the said portrait into the possession of several persons of rank, acquainted with the illustrious deeds of this far-famed Princess.

"But having invented quite a new and hitherto an unknown proceeding, I have been enabled to print from the copper, not thousands (as from common plates), but only a few, owing to the subtlety of the workmanship, for which reason I have only a small number of copies to present.

"Of course I first of all make application to your princely grace, especially in dedicating the same to you, according to the inscription at the bottom, and for the following reasons:—

"The first, in remembrance of your mother, because the said object cannot be but most agreeable to your grace, as being the nearest, nay, the only son of the reigning Prince,

"For the second, because I dare not omit dedicating a work of art so rare and never heard of before, to such an extraordinary amateur of the fine arts as your grace is.

"No engraver or no artist will be able to imagine how this work could be done, because, as your grace is aware of, hitherto only three different species of workmanship are seen, namely,—

"First, line engraving, or cutting;

"Secondly, etching;

"Thirdly, a very uncommon manner, called the dotting manner, with points altogether, but different and very troublesome, and, therefore, not much in use.

"The present manner, however, is none of those, though also consisting of little dots without a single line, and though some parts have the appearance of lines, the whole is altogether stippled.

"I ought not to omit to state this for the guidance of such an experienced connoisseur as your grace is.

"Recommending your grace to the Divine Providence and welfare, I also recommend myself, remaining your grace's most true and humble servant,

"L. DE SIEGEN.

"Amsterdam, 29th August, 1642."

The mezzotinto is a process altogether distinct from those previously mentioned, and was effected in the first place by puncturing or breaking up a uniform burr over the entire face of a copper plate, from which, if a print were taken, an impression in density of colour would be obtained equal to that required in the darkest parts of the picture to be copied. Upon this ground the subject to be engraved was traced, and by scraping and burnishing away the burr or dotted surface impressed in the face of the plate, either in part or wholly, the necessary gradations of light and shadow were obtained. This process, although affording facilities for covering large surfaces, did not admit of being applied on a small scale, so as to give detail of drawing or delicacy of outline, and was in the main inapplicable to the production of foliage, and when first practised was grey in colour and flat in effect. At a later period, with the view of facilitating the operations of the engraver, an instrument called a roulet was invented, and was used for the purpose of impressing a series of dots into the metal.

The first person who applied the mezzotinto process on steel was Mr. T. Lupton, who, in 1822, submitted a specimen of his work to the Society of Arts, and stated that in order to obtain the necessary ground on the steel plate he had been obliged to lay his ways in 80 or 90 directions, whereas in preparing or breaking up the surface of a copper plate from 24 to 40 ways were all that were required. The use of steel necessitated a much stronger hand and an increased number of ways in laying the ground, but the advantage of steel over copper was that from eight to ten times the number of prints could be taken.

AQUA-TINTA, a process of engraving which was used at the beginning of the present century.

is now rarely employed, was executed by a process of the following description:—The surface of the plate of metal to be engraved was equally covered with a finely powdered resin. The plate was then warmed, to attach the grains to the surface of the metal. A tracing of the design to be engraved was laid upon the resin, and the surface of the plate, after the whites had been stopped out, was submitted to the corroding action of acid, which, acting between the grains of resin, produced a granulation in the face of the metal plate. The light parts of the design were next stopped out, when the acid corrosion had been carried far enough. The darker parts of the design were again submitted to the action of acid, and this process was repeated till all the gradations from light to shadow, required by the design, were produced in the metal. A slight amount of burnishing and scraping of the plate so bitten in was then resorted to, to blend the several parts of the picture, and to heighten the lights where necessary. This process was carried to great perfection by Mr. Sandby about 1799. Such were the various processes in general use at the beginning of the present century, the whole being originally executed in copper. A growing demand for book illustrations, and a necessity for producing the engraving in a more durable metal, and one that would consequently yield a greater number of impressions, led to the introduction of the next process.

STEEL AND MACHINE ENGRAVING.—The invention of steel engraving is due to Mr. Perkins, who first introduced the art in America; his object being to increase the facility, cheapen the cost, and produce absolute identity in the manufacture of bank notes. In order to effect this, he etched or engraved a steel plate, or, more properly, a block of soft steel, by the ordinary process of line engraving. The plate or block was then hardened. A cylinder of very soft steel, of from two to three inches in diameter, was then rolled backwards and forwards under pressure on the surface of the steel plate, until an impression from the engraving was obtained in relief on the face of the cylinder. The cylinder so obtained was in its turn case-hardened, and by rolling the hardened die over the surface of a flat plate of copper or soft steel, an exact copy of the original engraved plate, with all its sharpness, was secured. This process being repeated, any desired number of plates could be obtained from the die. As the object first sought was the production of bank notes, and the cost of elaborate designs was great, a machine was invented in America by Mr. Asa Spencer, which was called a geometric lathe, and this was employed in the production of geometrical figures in combination with line engravings, as borders and ornaments on the face and back of notes. Mr. Perkins brought his invention to this country, where it was introduced and known as the "sederographic" process for multiplying copies of engravings. Soon after his arrival in this country he was joined in working his process by Mr. Heath, and they state, in 1821, "we cannot yet say how long a well hardened steel plate will last, having never printed more than 500,000 impressions from the same plate. It should, however, be observed that this plate consisted principally of writing, or work quite as strong. It may also be observed that the impressions are yet good." The first steel plate engraved in this country is attributed to Mr. Raimbach, who was soon afterwards followed by the chairman of the Fine Arts Committee of the Society of Arts, Mr. Charles Warren. Engraving on steel, beyond necessitating a change in the nature of the acids used, and a better and more perfect graver, involved but little alteration in the process of engraving itself. Steel plates yielded a much larger number of impressions, but they also demanded more time in their execution, and, as a consequence, a higher rate of remuneration for their production; and thence arose a class of men whose works as artists gave fashion to the art of engraving and book illustration; and out of their labours came such works as "The Forget-me-not," "The Keepsake," "The Book of Beauties,"

&c., &c., coupled with which works are the names of the Findens, Charles Heath, Rolfs, Lacy, the Le Keuxs, Goodall, Wilmore, Doo, and others, a school of engravers which has now entirely passed away. With the extended use of steel, however, came a proportionately heavy charge for printing, which, where large numbers were required, it was desirable to reduce as far as possible. This charge was not material as affecting high-priced works, but a considerable demand for illustrated books having arisen, a readier and cheaper means of illustration was required. We accordingly find that "Hone's Every-day Book" and "The Penny Magazine," which were popular works, and amongst the earliest examples of cheap literature, were illustrated with wood engravings, which, being produced in relief and capable of being printed with the type, saved the ordinary extra charge due to printing from steel plates. But, however artistic and effective wood blocks were, they lacked the refinement of the steel engraving. Concurrently with this spread of art in England, came the opening of the American, and the creation of an Australian market for English literature, and the adoption of a German discovery, which has done more to revolutionise art in this country than any other previously introduced, viz., the invention of lithography by Alois Senefelder, who, about 1795, while in search for a cheap means of printing the pieces which as a dramatist he produced, by an accident discovered that by writing on a slab of Kelheim stone, with ink prepared with wax, soap, and lamp black, and then biting in the stone with *aqua-fortis*, a surface in relief could be obtained, from which prints could be taken almost as easily as from wood blocks. This discovery led to the art of lithography as now practised. To the growth of the lithographic art I shall return hereafter, but for the present I would merely say that its introduction, and the great cost, as well as the time involved in printing from steel or copper plates, led to numerous attempts to cheapen the cost of engraved plates, and also to multiply the plates when produced. The process introduced by Mr. Perkins was inapplicable to large surfaces, both on account of cost, and the difficulty and risk of injury in applying it. But machinery had been applied in the form of the geometric lathe, and a desire was created to possess a machine of a simpler character which might be employed to produce skies and backgrounds in architectural subjects, as well as backgrounds to portraits, without involving the skilled, and in many cases monotonous labour of etching. This want was soon supplied by Mr. Lowry, who was speedily followed by Mr. Porter, Mr. Taylor, Mr. Storker, and others. By the first-named a machine was invented for ruling either straight or waved lines, which lines, when used separately, produced flat or graduated tints, and when used in combination produced the effect now so generally seen on the face of banker's cheques. Mr. Taylor's machine consisted of a square bed, upon which the plate to be ruled or engraved was laid, and over which a second bed was slid on or thrust. This bed was held in position by means of springs, which pressed against the inner side of a frame, over and attached to the upper and lower edges of the square bed of the machine. At the back or right-hand side of the machine was a solid block, to which was attached, on its centre, a female screw, in which worked a clamping screw. The motion of the machine was produced as follows:—A bar of iron, having at one end a pin fitted into a socket on the sliding bed, while its other end passed through a slot below the female screw plate on the back of the machine, and a clamping screw being brought down upon this bar, prevented the sliding bed being moved from its position until it was thrust forward by an index lever, placed at right angles to and connected with the iron bar. The degree of motion of the bed was then regulated by the distance through which the index lever was thrust, and this was determined by means of a screw-stop. Mr. Storker's machine had for its bed an inclined plane, over

which worked a second wedge-shaped bed, and the tint was ruled by gradually removing the thick end of the wedge from the centre or edge of the machine. In both cases, after motion had been given, to regulate the width of the lines to be ruled, a carriage, carrying a diamond point, was caused to travel above the face of the plate to be ruled, and the diamond being allowed to drop on to it, the line was drawn or etched. By substituting for the straight line in which the carriage travelled any required character of etched line, and causing the carriage carrying the diamond point to travel in it, a corresponding motion was communicated to the diamond, and the desired effect was thus mechanically obtained. But where lines were required to be ruled in perspective, the plate was fixed on a bed which revolved on a centre. The use of these and other similar machines was soon largely resorted to, and ultimately line engraving, as a commercial production, deteriorated; and in its place grew up a mere vulgar effect of light and shadow, the combined result of a set of lines ruled over the entire surface of a steel plate, and then acted upon by acid, as in the case of aquatint engraving. There were, however, other forms of machine engraving introduced, which have given rise to new industries, and continue still in use, such as the medallion engravings executed by Mr. Bacon's machines, in which a medal or modelled design was employed, and over the medal a tracer was made to travel, which varied in its direction from a straight to a curved line, in proportion as the surface was either flat or in relief. The background of the medal was represented in the engraving by a flat tint, while the high lights of the medal were produced by a widening of the lines, and the shadows by a comparative contraction of them. Modified forms of this machine are still in use, and have been applied to engrave rollers for printing calico and other fabrics. The result of these machine processes, coupled with the introduction of lithography, was to create serious competitors with the aquatint and mezzotint processes, which may be said to have been swept away by the great advance which lithography has made, to the consideration of which we will now return.

LITHOGRAPHY.—I have stated that Senefelder discovered, about the year 1795, the principle upon which lithography is based, but it was not till 1819 that much progress was made in the art; but at that date, owing to the fostering care of Baron Arctin, in Munich; Count Lasteyrie in Paris, and Mr. Rudolph Ackerman in London, an account of the art of lithography, showing its then state, appeared. The establishment of the art of lithography in England is, however, due to Mr. Hullmandel, who not only drew upon stone with crayons and printed from them in black ink, but soon carried out the process by drawing on two or three stones, and printed from them with ink of a neutral tint; he also drew on several stones, and printed from them in colours. Mr. Hullmandel introduced the process known as lithotint, the drawing being made upon the stone with a brush and liquid ink, and he also applied the process of stump drawing. The facilities which drawing with the crayon, the stump, and the brush, afforded for the production readily, and at a moderate cost, of a surface from which to print, soon gained for the art a large amount of public support, and enlisted the sympathies of the late Mr. Mulready, Mr. J. D. Harding, Mr. Louis Haghe, Mr. James Ward, Mr. J. Lane, and other Royal Academicians and artists, who applied themselves to the production of sketches on stone. There was, however, in the early attempts at lithography, a crudeness of effect and a want of gradation from light to shadow. To overcome this, Mr. Hullmandel made a material between ink and chalk, which, being applied to the hard edges, carried the full tints by gradation into the high lights. The effect thus obtained advanced the art in the estimation of artists, as it increased the facility for producing artistic effects, which was also greatly helped by the use of tinted paper and printing in neutral tints from several stones. Printing in colours was practised by Sene-

felder, but his early specimens give but a faint idea of the richness and beauty of the productions of Mr. Owen Jones, who applied himself to develop the powers of lithography, and who not only drew upon stone, but also printed in gold and colours the whole of his work illustrative of the Palace of the Alhambra. In addition to drawing on stone and printing in flat colours, he introduced a method of printing from graduated tints drawn in ink only upon the stone, graduating his tints by stippling upon polished stones with a fine camel hair pencil.

Litho-tinto is a method of drawing, in which washes of ink are applied to the surface of the stone, but it is not largely in use, though many artists have employed the process in the reproduction of their own sketches. The process of stump drawing by Mr. Hullmandel afforded great facilities for the production of even and graduated tints over the stone, and soon became a process in general use. The cost and inconvenient weight of the lithographic stone led to a desire to find a substitute, and for a large amount of commercial work drawing on zinc has been found to answer, and is now extensively in use. This fact leads me now to refer to the commercial, rather than the artistic use of lithography.

I have said that the discovery of lithography gave a means of printing from the surface in a manner similar to the process of printing from type or wood blocks, but owing to the slight relief of the drawing on the stone, and the necessity for wiping with a wet sponge, and gumming the surface of the stone to prevent the absorption into the stone of the grease from the ink, the process is nevertheless a tedious one, but this evil is in a measure compensated for, by the facility which the lithographic process affords for multiplying copies of a drawing when once made, by transferring an impression taken from the drawing first made to a second portion of the stone, and as this can be repeated to any extent, a number of copies can be printed at one operation—the only limit being the size of the stone, and the nature and size of the design to be printed. The want of an efficient substitute for steel and copper plates, in the form of a surface block from which to print with the type in ordinary type printing presses, still remains a desideratum, notwithstanding all that lithography has done, and the many attempts which have been made. Casts in relief from engraved copper plates were among the earliest efforts in this direction, but the cost and labour of producing a uniform surface fit for the printing press, has not hitherto led to a commercial success.

ELECTROTYPE.—We now come to a period in the history of engraving at which another new discovery was given to the world, and one which has since played an important part in the arts. I refer to the discovery of the process of electrotyping. In the year 1800, Volta, in a communication to the Royal Society, announced his discovery of the Voltaic pile. By its means Nicholson effected the decomposition of water and of several metallic salts. Cruikshank next invented the galvanic battery, to the positive poles of which he attached silver wires, the other ends of the wires being placed in a glass tube containing a solution of acetate of lead. When the electric current had passed through the solution for some time, metallic lead was found deposited on the negative pole. Brugnatelli observed the transfer of the elements of a decomposed compound from one pole to another. In 1801 Wollaston made the following observation, viz.:—That if a piece of silver, in connection with a positive metal, be put into a solution of copper, the silver is coated over with the copper, which copper will stand the operation of burnishing. It was not, however, till after the discovery by Daniel of his constant battery, in which copper is continually reduced upon the negative plate, that it was observed that the newly-deposited copper, when stripped off, had upon it a counterpart of every scratch on the plate upon which it was deposited. In 1837, Mr. Spencer, of Liverpool, discovered that if a portion of the surface

of the negative plate was covered with varnish, then no deposit took place upon those parts. He next conceived the idea of applying this process to the arts, by coating a piece of copper with varnish and wax, and cutting a design through it so as to leave the copper bare, and then depositing a metal upon these parts, so that on removing the varnish the design would be left in relief; but no account of these experiments was published till September, 1839. In May of that year it was announced in the *Athenæum* that Professor Jacobi, of St. Petersburg, had discovered a method of converting any line, however fine, if engraved on copper, into a relief by a galvanic process. This announcement was followed by a letter from Mr. C. J. Jordan, which appeared in the *Mechanics' Magazine* in June of the same year; and it is due to Mr. Jordan to state that the suggestions he then made have since been acted upon with considerable success. Mr. Robert Murray next discovered that if the surfaces of plaster casts and similar non-conducting bodies were covered with plumbago or black-lead, it was no longer necessary to use metallic moulds, which had hitherto proved the great barrier to the progress of the electrotype art. Chemists and artists were not slow in their endeavours to apply this newly-discovered process as a means of multiplying copies of engraved plates, both of copper and steel. In the latter case, an impression was taken from the steel-plate, by covering it with a sheet of tin-foil, and passing it through the printing-press. The result was a print obtained in relief on metal. Upon this a deposit of copper was made of the required thickness, and the required plate from which to print was obtained. In the early experiments the plates were thin, and curled in printing; this defect was, however, soon overcome, and the practice of engraving in copper, where large plates were to be produced, as in the examples issued by the Art Union, was again soon reverted to, thus affording facilities which are now largely availed of, for multiplying copies of costly engravings at the same time that the quality of the works produced can be maintained against wear.

GLYPHOGRAPHY.—The next application of the electrotype art to which it is necessary to refer, was that patented by Mr. Edward Palmer, and introduced under the title of "glyphography, or engraved drawings for printing at the type press after the manner of woodcuts." The process was a compound of drawing and engraving on a plate of copper, the surface of which, having been stained black, was then covered with a thin layer of a white opaque composition. A tracing of the design to be drawn or engraved was made. Needles, of various degrees of breadth and form, were then employed to remove the composition from the surface of the copper, beginning with the greatest breadths of shadow, and gradually working up to the lighter and more delicate parts of the design. When finished an electro deposit was taken from the drawing so made, and a block in relief was thus obtained, which, being mounted in the same manner as an ordinary stereotype plate, was capable of being worked in with the type, and printed from, in the machine and steam printing press. It is necessary to state that the composition on the face of the plate was extremely thin, and in order to obtain the required relief for a printing block, recourse was had to a secondary process for increasing the amount of relief in the blocks, and this was done to any desired extent. The specimens which Mr. Palmer presented to the world, of work produced by this process, left little to be desired so far as artistic effect was concerned; but as the process has not become general, I fear the cost of producing the blocks was not commercially economic. Among the artists who first applied this process may be mentioned Thomas Landseer, J. Bateman, W. S. Wilkinson, Alfred Crowquill, J. Fraser Redgrave, and W. H. Pain. This process is not so generally known as its merits and capabilities entitle it to be, and the problem of how to obtain with facility a substitute for the wood block still remains unsolved. Among the

numerous other plans proposed for use in the production of engraved plates or blocks, may be mentioned voltatype, electro-tint, daguerreotype, and etching by galvanism.

ETCHING BY GALVANISM was suggested by Mr. Alfred Smee; it was similar to the ordinary process of etching, but instead of being bitten in by a direct acid action, Mr. Smee suggested that the etched plate should form the positive pole of a battery, and being dipped in a galvanic trough of sulphate of copper through which a current was passed, particles of copper would be given off from the etched lines of the engraving; the plate was to be removed from the bath from time to time, for the purpose of stopping out, and graduating the tints required, as in the usual etching process. Mr. Smee considered that the advantages of his galvanic process are the absence of nitrous fumes, greater uniformity of action than when acid is used, greater rapidity of biting, and at the same time any required depth of line can be obtained and the lines themselves will be sharper and cleaner, owing to the etching ground not being torn up by air bubbles. I am not aware that the suggestion of Mr. Smee has ever been commercially applied, but he has continued his investigations. In 1851 he presented a report to the governor of the Bank of England, in which he stated that he considered the time had arrived when surface printing from electrotype blocks could be advantageously employed in the production of Bank of England notes. His proposition has since been carried out, and at the present time Bank of England notes and cheques are so printed. I would not have it inferred from this fact that what is economic and available for Bank of England purposes, is either expeditious or commercially available. Those who desire full details of the process employed by Mr. Smee in the production of surface blocks, I would refer to a paper read by him before the Society of Arts, on the 20th December, 1854, and which is published in full in Vol. III., page 81, of the *Society of Arts Journal*. Etching by galvanism forms the connecting link between electro engraving and the daguerreotype art.

ETCHED DAGUERREOTYPES.—The discoveries of Mons. Daguerre were first formally communicated to the world by M. Arago, who, on the 7th January, 1839, read an account of them before the Academy of Sciences in Paris. The invention consisted in the discovery of a process whereby the image obtained in the camera obscura could be permanently fixed on a metal plate. The process soon became known as the daguerreotype art, and its results as photogenic drawings. These were produced upon plates of copper coated with silver. The silvered surface was then washed with a solution of nitric acid, after which it was placed in a closed box, where it was subjected to the action of the fumes of iodine. An ioduret of silver was thus formed. Thus sensitised the plate was next exposed to the action of the rays of light within a camera, when the image to be copied became impressed upon it, and was then permanently fixed by immersing it in a bath of hyposulphate of soda. Having been well washed with clean water, it was capable of being exposed to ordinary daylight without injury. Mr. W. R. Grove, in 1841, described his method before the Electrical Society, and stated that he used dilute hydrochloric acid in the galvanic trough, having first coated the daguerreotype plate with gold, which amalgamated with the mercury on the surface of the plate, and that this acid, by acting unequally upon the different parts of the daguerreotype plate, according to the extent to which the light and the mercury had before acted, bit it away in the manner of an etching, so as to produce deep lines in the shadow parts and fainter ones in the light tints. The proposition of Mr. Grove was not lost sight of by Mr. Claudet, Mr. Fox Talbot, and others, who early made attempts to engrave and print from the daguerreotype plates, but the delicacy of the surface of the plate, and the nature of the subjects selected, prevented the process from being practically adopted. Subsequent discoveries, and the art of photography, to which I shall presently refer, have, nevertheless, produced some of the most perfect

examples of engraving by the combined action of light and electricity.

I must now retrace my steps and recall attention to the discovery of Mr. Murray, who, having succeeded in giving a conducting surface to non-metallic bodies by the use of plumbago, placed within the reach of the scientific man a new and as yet unheard of process of engraving, which is now known as Nature Printing. The first examples of this art were also due to the discovery and use of a substance made known to the world through the Society of Arts in 1848—I mean gutta percha.

NATURE-PRINTING, as it is called, was first introduced to the notice of the public through the Society of Arts, which, in its notes of proceedings for the year 1849, printed a communication from Dr. Ferguson Branson, of Sheffield, in which he stated he had ascertained that by embedding a fern leaf, or any other flat body in softened gutta percha, and then allowing the gutta percha to cool, upon removing the leaf a perfect mould was obtained, from which mould an engraved copper-plate fit for the printer could be secured by means of the electrolytic process. A plate so obtained, with prints taken from it, accompanied the communication. Nature-Printing, however, did not long remain in this normal condition, for in the Exhibition of 1851, in the Austrian department, were exhibited specimens of plants, flowers, &c., printed in colours from copper plates. It had been ascertained that if a rolling pressure was employed to embed the object to be copied, that then soft sheet lead could be used, and that process was subsequently introduced into this country, and employed by Mr. Henry Bradbury in the production of his work on Ferns and Mosses. Nature-printing did not stop here, for in a communication read before the Society of Arts in 1854, by Mr. Aitken, of Birmingham, we find that, by means of a rolling pressure, objects of various kinds, and of the most delicate description, such as thread-lace, the down of a feather, &c., could be made to engrave itself in Britannia metal, copper, brass, German silver, or tin plate, and to use Mr. Aitken's words, "more wonderful still, on what we are led to believe is the most dense and hardest metal in ordinary use, viz., steel." Mr. Aitken pointed out some novel and interesting applications of nature-printing then in use at Mr. R. F. Sturge's works at Birmingham, in the ornamentation of metal surfaces, by means of patterns cut out of sheets of paper, and placed between two plates of soft metal, and passed through the rolling press. The effect produced was that of a burnished figure in relief upon a frosted ground; this resulted from the contact of the two metal surfaces, which burnished each other; but the paper, being embedded in the two metals, gave to the surface of the metal round the pattern a grain which may be described as a print from the pulp of which the paper was made. I must not, however, here enter upon the industrial and manufacturing uses to which electrolytic deposits and nature-prints have been applied, but will direct attention to another process, in which the principle of nature-printing has been proposed to be applied as a substitute for engraving—I mean the process submitted to the Society by Mr. George Wallis, and called by him Auto-typography. In this process Mr. Wallis substitutes for, or in combination with, a natural object, a drawing made upon a surface of gelatine. This he selects as it has no grain, and is to a great extent non-absorbent. His drawing is made with an ink or fluid, which, when dry, either crystallises or forms a naturally-granulated body in relief upon the surface of the gelatine. The drawing, having been carefully prepared, is then passed through a press, in contact with a metal plate, into the surface of which the drawing becomes embedded, and the result is a transcript in copper of the artist's own drawing, from which prints may be worked in the usual manner. Notwithstanding the suggestions above related, I regret to say we are still without that great desideratum, a surface block, or a ready means of

obtaining one, at a commercially economic rate by a process which will give to the artist a true translation of his sketch or finished drawing, to the commercial world an economic means of extending a knowledge of art, and of cheapening the cost as well as extending and facilitating the means of book illustrations, and to the public the advantage of a ready means of cultivating economically a knowledge and a love for all that is elevating and beautiful, both in nature and art, as well as a means of educating the youth of our country by means of cheaper, more numerous, and better examples than are at present generally attainable. But before I close this communication, which I propose to do by referring to other processes which I think deserve more attention than they have hitherto received, and which I believe to be capable of helping to solve the problem of how to obtain a surface block, I must, in justice, refer to the photo-galvanographic process of Mr. Paul Pretsch, the photo-lithographic process of Colonel James and others, and the process for enlarging and reducing drawings and engravings patented by Mr. H. G. Collins. I have already spoken of the efforts which Mr. Grove made to engrave the image obtained upon the daguerreotype-plate, and it is due to Mr. Archer, who was the first to propose the use of collodion as a medium upon which light might be made to impress an image, that I should state that it is to that gentleman's discovery that the world owes its present advanced position in the art of photography.

PHOTO-GALVANOGRAPHY.—Without the collodion film Mr. Paul Pretsch's photo-galvanographic process of engraving would not have existed, as light could not be transmitted through the daguerreotype plates, and the paper processes of Mr. Fox Talbot and others would have been inadmissible. Mr. Pretsch knowing that gelatine, if treated with bi-chromate of potash and submitted to the action of light, possessed a power of expansion, and availing himself of that fact, used a photographic image taken on collodion as a means of partially intercepting the rays of light, thereby regulating their action upon sensitised gelatine, and as a result he obtained a positive photographic image in relief in gelatine. The image, being allowed to dry, was then coated with black lead, and served as a mould in relief upon which to deposit, and from which he obtained by electro-deposition an engraved copper plate of the original collodion photograph, from which plate-prints could be taken as in ordinary copper-plate printing; and it is right to add that some of the best specimens of prints from chemically-engraved plates ever seen were so obtained and introduced into commerce. But the fault which attached to the aquatint and mezzotint processes of engraving, also attached to Mr. Pretsch's process, viz., the surface or grain of the plate was too fine to yield a large number of good impressions, and that is no doubt one of the many causes which have impeded its extended use. The acierage process of M. Joubert for coating copper plates with an iron surface (described below), was not introduced at the time Mr. Pretsch was working his invention. Mr. Pretsch succeeded in producing surface blocks by his photo-galvanographic process. In order to obtain a surface block, it must be borne in mind that the process, as compared with the intaglio plate, is reversed. In the engraved plate the impression is printed from the lines cut into the plate, but in the case of all surface blocks, it is the portions which are not to be printed from which have to be removed by the graver. In like manner Mr. Pretsch used a negative photograph in one case and a positive in the other, thus reversing his results.

ACIERAGE.—The acierage process is thus described by M. Joubert:—

"My invention has for its object certain means of preparing printing surfaces, whether for intaglio or surface printing, so as to give them the property of yielding a considerably greater number of impressions than they are capable of doing in their ordinary or natural state. And the invention consists in covering the printing sur-

faces, whether intaglio or relief, and whether of copper or other soft metal, with a very thin and uniform coating of iron, by means of electro-metallurgical processes.

"It having become a desideratum to harden, if possible, the surface of a copper plate, and to protect it from wear while printing, in March, 1848, my friend, M. Jacquin, of Paris, took out a patent in this country for a method of coating plates with iron, which had already been successfully applied in France, and of which the merit is due to my friend, M. Henri Garnier, of Paris.

"I have myself had the advantage of co-operating with M. Garnier in the development of the invention, the principles of which I shall now proceed to describe:—

"If the two wires of a galvanic battery be plunged separately into a solution of iron, having ammonia for its basis, the wire of the positive pole is immediately acted upon, while that of the negative pole receives a deposit of the metal of the solution—this is the principle of the process which we have named "acirage."

"The operation takes place in this way:—By placing at the positive pole a plate or sheet of iron, and immersing it in a proper iron solution, the metal will be dissolved under the action of the battery, and will form hydrochlorate of iron, which, being combined with the hydrochlorate of ammonia of the solution, will become a bichloride of ammonia and iron; if a copper plate be placed at the opposite pole and likewise immersed, the solution being properly saturated, a deposit of iron, bright and perfectly smooth, is thrown upon the copper plate, from this principle:—

"Water being composed of hydrogen and oxygen;

"Sal-ammoniac being composed of

"1st. Hydrochloric acid containing chlorine and hydrogen;

"2nd. Ammonia, containing hydrogen, nitrogen, and oxygen;

"The water is decomposed under the galvanic action, and the oxygen fixes itself on the iron plate, forming an oxide of iron; the hydrochloric acid of the solution acting upon this oxide forms a hydrochlorate of iron, whilst the hydrogen precipitates itself upon the plate of the negative pole, and, unable to combine with it, comes up to the surface of the solution in bubbles.

"I would remark that it is important that a ferric solution should be employed which will not dissolve or corrode the plate intended to be coated, for if it be attempted to use such a solution, though the iron will be precipitated, it will not only be in a non-coherent state, but the engraved surface itself will be liable to be attacked and injured. It may also be remarked that the coating of iron admits of being removed from a printing surface of copper without injury to the original plate, hence the original plate may, after being coated and used for some time, have the worn coating removed, and then be recovered with an iron coating as often as may be required."

PHOTO-LITHOGRAPHY.—Colonel James, of the Hydrographic Department of the Government, has introduced and used a process of photo-lithography, to which I cannot do more than allude. It is similar, in many respects, to the photo-lithographic and zincographic process described by Mr. John Walter Osborne, in the *Photographic Society's Journal*, vol. 7, pages 163 and 213, as follows:—

"In the first instance, a sheet of paper is prepared with albumen, in the usual way known to photographers; it is, when quite dry, passed through a copper-plate or lithographic press, upon a polished steel or copper-plate, by which operation it receives a very smooth and regular surface; it is then coated on the same side with a solution of gelatine, to which an addition of bichromate of potash has been made; this is then carefully dried in the dark, and again passed through the press to ensure the finest surface. This operation completes the preparation of what I shall call the sensitive paper. Having made a negative of the original map bearing the desired proportions to it, I place a suitable piece of the sensitive paper just described under and in close contact with the map,

and the whole is exposed to daylight in such a way that the luminous influence passing through the transparent parts of the negative, shall strike directly upon the prepared surface, while the greater part of the paper is protected from its influence by the dark parts of the negative, which correspond to the white places on the original map. In the presence of the organic matter, the actinic agency effects the decomposition of the bichromate of potash, and the liberated nascent oxygen in all probability reacts upon the gelatine, altering its chemical characteristics in a peculiar manner. The visible effect, after removing the negative, is the formation of a picture in brown, upon the clear yellow of the paper, corresponding to the transparent portions of the negative, or to the black lines on the original drawing.

"This positive photographic print is next covered with an even coating of lithographic transfer ink, by passing it through the press, face downwards, upon an inked-in lithographic stone; the pressure causes the whole of the sensitive surface to lay hold of the ink, and bear away with it an even coating, hiding the brown photographic positive from view. The altered parts of the gelatine which have been exposed to the luminous action, appear to be possessed of a certain amount of affinity for the grease of the ink, so that they will be found to retain it with considerable tenacity.

"The next operation is to coagulate the albumen which still exists under the prepared surface; this is done by floating it upon boiling water, with the paper side downwards. A subsequent soaking for a short time causes the unaltered gelatine to swell in such a way as to raise the ink with it from the paper; and a slight amount of friction, with a sponge or other soft substance, removes the superfluous ink from all parts of the inked print which correspond to the white parts upon the original document. When the lines appear clear and well defined, boiling water is poured over the whole, to remove the last traces of gelatine, and the print is dried. We are now possessed of a *bond fide* lithographic transfer, that is, a drawing, in greasy ink, of such a nature that it admits of being transferred to the stone in the ordinary manner, by simply inverting it thereon, and passing it through the press,—the albumen, which will be found to have withstood all the washing, acting as the adhesive substance under the ink to prevent the paper slipping on the stone.

"The whole of these operations need not occupy more than from two to three hours."

PROCESS FOR ENLARGING AND DIMINISHING ENGRAVINGS.

—Mr. Collins' process for enlarging and diminishing drawings or engravings was chiefly mechanical and lithographic. The plan was as follows:—A print from any engraved plate, wood block, or lithograph, was taken in the ordinary manner, but in transfer ink, and upon a sheet of vulcanized india rubber, covered with a composition of equal elasticity, and of a non-porous character. If it were desired to enlarge the design, the india rubber upon which the impression had been taken was attached to a frame by means of hooks passing through holes made at equal distances round the edges of the india rubber. Four bars were then passed through the body of the hooks, and the sheet was thus prepared for the extending machine, which consisted of two parts, viz., a table and screws, the latter being used to stretch the rubber equally to the required dimensions. The impression was then transferred and printed by the ordinary litho or zincographic processes. If the design was to be reduced, the india rubber was stretched before the impression was taken upon it, and afterwards allowed to contract to the required dimensions in the regulating machine. Mr. Collins considered that his process would afford a ready means of adapting a design, when once made, to the size and character of the same work when printed in editions of various size of page. Mr. Collins, however, found the lithographic process of printing a great impediment in the way of his progress, and attempted to obtain a surface block by building up the impression transferred to

re, by depositing a succession of layers of printing ink, dried with suitable dryers, and when such building up of the ink had been carried sufficiently far, a cast in some other material was taken, and from the cast so obtained a copper block was secured by electro-deposition. This process was tedious and uncertain in its results, and the predecessors, failed to secure the object aimed at. I cannot help expressing an opinion that one great cause of failure in the majority of the plans proposed has been, that the authors of them have been too hasty in the selection of subjects, or almost entirely ignorant of the art of engraving. They have endeavoured to arrive at perfection at once, and have consequently crowded in composition and too full of detail, the result has been a deficiency of definition, a want of relief, and an entire absence of artistic effect, due to the irregular gradation in the lights and shadows. Several plans which have been proposed are probably capable of yielding good results, if the attempt to apply them is confined in the first instance to sketches in outline, a class of art but little practised, but one which is most capable of affording the highest gratification and of employing the most skilled artists. By beginning with the outline, experience in manipulation would be quickly acquired, and a chiaro-oscuro effect ultimately attained to if desired; and I have little doubt that sketches in outline can be readily produced, either by the electro-magnetic or mechanical process of Mr. Hansen, or the more recently-discovered processes of M. Vial and Dulos.

ELECTRO-MAGNETIC ENGRAVING.—The process of Mr. Hansen is as follows:—The drawing which is intended to engrave is made on a metallic or non-metallic surface, with a resin ink, or some other conducting substance. As soon as the ink is hardened, the plate with the drawing is placed on a moveable table or bed of a machine, side by side with a plate to be engraved. The machine is constructed somewhat on the principle of the planing-machine. A pointer or feeler is so connected by means of a horizontal bar with a graver, that when the bar moves, the drawing to be copied passes under the graver, and the plate to be engraved passes in a corresponding manner under the graver. The plate is moved by placing the graver under the control of two magnets, acting alternately—the one to draw the graver from the plate, the other to press it upon it. The drawing being made on a conducting surface, an electric current is established, so that the feeler or tracer which passes over the plate, with which it rests on the metallic surface, it passes through the coils of the magnet, and causes it to lift the graver from the plate, but when it reaches the non-conducting ink of the drawing, the current of electricity is broken, and the magnet ceases to act, and, by a self-acting mechanical arrangement, the graver is at the same time directed through the coils of the magnet, which then acts powerfully, and presses the graver down into the plate. This operation is repeated again and again, till the entire surface has been engraved to a uniform depth by the graver, by passing it over the lines over the entire surface of the drawing. When the plate so engraved a type metal cast is taken, which being a reverse, in all respects, of the engraved plate, is at once fitted for use as a block for surface printing.

M. VIAL'S INSTANTANEOUS ENGRAVING.—The process proposed by Mons. Vial to the Society has been so recently published (Vol. xii., p. 179), that I need do little more than refer to it, and my reason for doing so at all is for the purpose of pointing attention to the fact that Mons. Vial proposed to engrave plates by biting in the design, not on that portion of the steel plate which was covered with copper. The question which I have to ask is not Mons. Vial reverse his process, by making the steel to be engraved with a material which shall de-

posit the necessary protecting surface of copper on the steel, allowing the blank surface of the steel plate to remain open to the decomposing action of the sulphate of copper and nitric acid, thus giving as a result the drawing in relief on steel. Casts could then be taken, from which electro blocks could be readily obtained, and if the minutely granulated surface of a daguerreotype plate was capable of being coated with gold, and bitten in by hydrochloric acid sufficiently deep to admit of being printed from, I can see no reason if M. Vial takes an outline subject, and applies a similar process, why he should not readily produce a good surface block.

M. DULOS' CAPILLARY PROCESSES.—The last processes to which I have to allude are those recently submitted by M. Dulos to La Société d'Encouragement, Paris, and a full report of which will be found in vol. xi., of the Bulletin of that Society. The report is accompanied by prints illustrative of the results obtained by the methods which he employs, and as these have not hitherto been published in this country, they will doubtless be read with interest. M. Dulos' process is based on the phenomena of capillary attraction; thus, if lines be traced with varnish on a silver or copper plate with a silver surface, and mercury be poured over it, duly levelled, the mercury will attach itself only to the parts not covered with varnish, and will stand up and form a slightly convex wall on each side of the lines traced on the plate. A similar effect takes place if the experiment be made with a ground glass surface using water or some other liquid instead of mercury. Take, then, a copper-plate with a silvered surface, and transfer to it or draw upon it, by means of lithographic ink, any design whatever; then cover the plate by means of the galvanic battery with a thin film of iron, which, of course, will only be deposited on the parts untouched by the ink. The ink is cleared off by means of turpentine, and the plate then presents a surface of iron with the lines of the design in silver. Mercury is then poured on the surface, and it attaches itself only to those portions of the plate which are silvered. The excess of mercury having been removed with a soft brush, the metal remains in relief. From this a mould may be taken, and, by means of the electrotype, a copper-plate may be deposited, and this will be an exact copy of the original plate, having the lines in relief. This will serve as a matrix from which intaglio plates may be multiplied to produce impressions in the ordinary way. If plates for surface printing are required, a copper-plate receives the design, as before, in lithographic ink, varnish, or other material, and the plate is then, by means of the galvanic battery, coated with a thin film of silver, the film only attaching itself to the parts not drawn upon. The ink is then removed by means of benzine or turpentine, and we thus obtain a plate in which the design appears in copper on a silver plate. The plate is then bitten in by acid, which attacks only the copper lines, the rest of the plate being protected by the surface of silver. The rest of the process proceeds as before. Such are the principles and outlines of M. Dulos' process, which he has now brought to practical working by adopting various modifications and details. Thus he replaces the mercury by an alloy fusible at a low temperature, such as that known as the fusible metal of Arcet, to which he adds a small quantity of mercury. This alloy, when poured over the plate in a melted state, acts precisely as the mercury does, but becomes hard when cold, thus at once forming a plate from which an electrotype copy may be made. This operation, however, must not take place exposed to the air; the plate should be placed under a layer of oil heated to 80° (176° Fahr.), the temperature at which the alloy melts. Oxidation of the surface is thus prevented, which would otherwise injuriously affect the process. Special means are, however, required for removing the excess of either the mercury or the fusible metal, without which the finest lines cannot be retained. An amalgam of copper is found advantageous in the place of either mercury or fusible metal. On the plate, with the design or

treated as above, the amalgam is applied by means of a roller of silvered copper, which takes up all the amalgam lying free on the iron surface, and transfers it to the silvered portion. As soon as the amalgam sets an electrotype copy can be taken. M. Dulos suggests another modification, which depends on the property of silver to attach itself more easily to mercury than copper does, and the following is the mode proposed:—After having drawn the design on a copper plate with lithographic ink, the plate is silvered, and the ink washed away as before. If the plate be now plunged into a bath composed of a salt of mercury, say the sulphate, a chemical reaction takes place, by which the mercury becomes deposited on the silvered portion and the sulphuric acid attacks the coppered portion, or lines of the drawing. This operation, which lasts only a few minutes, forms lines in the copper, the sides of which are preserved by the transfer of the mercury from the copper to the silver. There is no more difficulty in drawing on the copper with the lithographic ink than on stone; and a drawing made in this way can be transformed into an intaglio, or surface plate, as may be required.

The following is a resumé of the processes used by M. Dulos.

Intaglio Plate.—The plate, drawn upon in the manner described, receives a coating of iron by means of the battery; the ink is then washed off, and it then receives, by means of the battery, a deposit of silver, which will only take place on the parts not covered with iron, i.e., the parts drawn with the ink. A silvered copper roller, covered with amalgam of copper, is then applied to the surface of the plate. The amalgam attaches itself solely to those portions of the plate which are silvered, and leaves the iron uncovered. As soon as it solidifies an electrotype plate can be taken from it in copper which is ready for the press.

Surface-Printing.—The plate, and the design on it, as before, has a layer of silver deposited on it. The ink is then washed off, exposing the lines in copper, which then is oxidised by heating the plate. The silvered roller with the amalgam is then applied, and the amalgam attaches itself only to the silvered portion of the plate; and, on its becoming solidified, an electrotype copy is taken, which of course produces the lines of the drawing in relief, and a surface-printing block is thus produced, ready for the press.

Intaglio Plate.—This plate may be produced by using a salt of mercury instead of the amalgam. The plate with its design is silvered, and the ink is washed off as before; it is plunged into a bath of an ammoniacal sulphate of mercury, and whilst there the silvered roller is passed over its surface for four or five minutes. The mercury, by a chemical reaction, is precipitated on the silvered portion, and the plate is at once ready for printing from.

Surface-Printing.—A salt of mercury may also be used for this process; thus, the plate is drawn upon, coated with iron, washed and silvered as before, and is deprived of the iron by means of acidulated water. It is then plunged in the ammoniacal sulphate bath, and whilst there it is rolled for four or five minutes; the lines of the drawing are at once formed in relief. The plates thus formed may be at once placed in the printer's hands.

Aquatint.—The ordinary aquatint grain having been given to a copper-plate, a copper-plate in reverse is taken from it by the electrotype process. This plate is then silvered, and the drawing is made on it with the lithographic ink, the whites or high lights being produced by the scraper. A layer of iron is then deposited, and the ink washed away as before, and the roller with copper amalgam applied. From this an electrotype plate is made for printing, the hollows of which reproduce the original aquatint grain, the drawing, and high lights produced by the scraper. M. Dulos describes also another process, both for copper-plate and surface printing, in which he uses a white varnish (*vernis blanc*). The plate is covered with a varnish

formed of caoutchouc and zinc white, which is readily cut through either with a quill pen or an ivory point, with which the design is traced on it. It is then plunged into the iron bath, and a thin film becomes deposited on the lines thus cut. If an intaglio plate be desired, the varnish is then washed off by means of a solvent, and the plate silvered, the silver only attaching to the copper surface, and not to the iron forming the design. The iron is then dissolved off the plate with diluted sulphuric acid, and the plate is treated with the mercurial salt as before. If a surface plate is desired, then the depositing the iron and silver is reversed. The copper amalgam may also be used if desired.

My object in writing this paper will have been attained if I have succeeded in showing the relation of the various art processes to each other. I have endeavoured to point out how each succeeding process has aimed at facilitating the means of reproducing and giving permanence to art, and a larger commercial product at a smaller cost to the producer and consequent advantage to the public. I have further endeavoured to show the methods which have been introduced, and the attempts which have been made to obtain more readily a true interpretation of the artist's conception, and nature's imprint of itself by means of a combination of lithography, photography, electricity, magnetism, and electrotypes, nature prints, and the amalgam of metals. Each process has been applied in the attempt to produce a surface-block from which to print. Hitherto, a commercial success has not been attained to, and my hope is that a knowledge of what has been done may cause others to carry on the investigation of this subject to a successful issue.

Fine Arts.

PUBLIC MONUMENTS.—A grand memorial work is to be raised on the spot lately occupied by the Barrière de Clichy, to commemorate the brave defence made there under Marshal Moncey, in 1814, and the project has been submitted to public competition. Twenty-seven designs were sent in and six were chosen, the authors of which were invited to compete again amongst themselves. The prize has fallen to M. Doublemard. The principal group represents the Marshal protecting with his sword an allegorical figure of the City of Paris, and being supported by four other figures—a garde national, a man of the people, a polytechnic student, and a pensioner—these four classes having been conspicuous in the affair.—The subscription opened for the erection of a monument to the painter, Hippolyte Flandrin, in the church of St. Germain des Prés in Paris, has produced the sum of eleven thousand francs (£440), but as the work, designed by M. Baltard, is calculated not to cost so large a sum, it is proposed to apply the balance to the production of a repetition of the bust of Flandrin by Oudinot, to be placed in the Museum of Lyons, of which town the deceased artist was a native.—A colossal statue of Vercingétorix, the celebrated Gallic chieftain, is about to be raised in the town of Alise, the ancient Alesia, where that hero made a desperate resistance to Julius Cæsar. This statue is about twenty feet high, and the work of M. A. Millet, the author of a beautiful figure of Ariadne, of a fine bust of Madame Pauline Viardot, a memorial statue of the late Henri Murger, author of the "Vie de Bohème," and other well-known works. The model of the head, which was exhibited a short time since in the public gallery on the Boulevard des Italiens, promises well for the work. The difficulty and expense of executing such a gigantic work either in stone or bronze, have led to the adoption of an old and most artistic method, that of *repoussé* work, applied of late years almost exclusively to ornamentation, to architectural figures to be placed on churches and other high buildings, or to designs of a

peculiarly simple form, such as angels with long flowing drapery, for organ fronts and other similar applications. In the case in question the difficulties will be considerable, for the model is characteristically picturesque in its treatment; the lines of the statue are broken and complex, with the details in sharp relief, the draperies flying, the hair floating in the breeze, and the hands grasping the hilt of a huge sword with all the savage energy of a hero at bay. A considerable portion of the work is done, and report speaks highly of the effect as far as it can be judged at present. The *repoussé* work has been entrusted to M. Aubert, an artist who has practised that method with great success. It will be remembered, by those who take a special interest in such matters, that a *repoussé* figure of about the same size of the one in question, the work of a German artist, was exhibited for some time beneath the porch of the central entrance of the Great Exhibition building in 1862. The *Vercingétorix*, when finished, will weigh about five tons, including the iron skeleton which is to support the thin colossus. It is to be mounted on a granite pedestal, of a size proportionate to itself, and the whole will stand on a small hill, so that the profile of the figure will be seen against the sky in every direction.

THE RIGHETTI HERCULES.—The fine bronze statue of the youthful Hercules, found during the excavations beneath the Righetti Palace in Rome, about the destination of which so much has been said, has really become the property of the Papal Government. It is said that the Emperor of Russia offered to become the purchaser for a sum equal to £14,800, but that the fortunate possessor, Count Righetti, made it a present to the Pope, and that the Pontiff, not to be outdone in generosity, immediately ordered the sum of 2,500 crowns to be entered in the records of the Holy See as annuity to the Count and his

family. His Holiness is also said to have presented the Count's son with a rouleau of gold, and it is added, moreover, that the donor of the statue is to be raised to the dignity of a marquis. Such is the account at present current of the transaction.

Manufactures.

DIRECT-ACTING STEAM TILT-HAMMER.—At the ordinary meeting of the Society, on the 23rd of November, a model of a tilt-hammer, the invention of Mr. Henry Reveley, was shown. The following detailed description will be interesting to the members:—It will be seen, by inspection of the accompanying cut, that the principle of action is that of the broken lever, or knee-joint, and that the hammer is lifted, or thrown to its extreme height, at every half-stroke of the cylinder by means of the piston-rod, which is connected with, and forms part of the knuckle-joint. It will also be readily seen that the arrangement resembles, as closely as possible, the muscular power of the arm and shoulder of the hammerman, when he brings down the adledge with accelerating velocity upon the point of impact. The diagram is on a scale of one-third of an inch, reduced from the working model on a scale of one inch to the foot. The dotted lines show the knee joint in its three positions of front and back stroke, and at the point of greatest elevation, when the hammer is in a state of perfect repose, owing to the knee-joint being then perfectly straight. The driving power must be a vibrating high-pressure cylinder, with the usual jacket and slide valves, but no hand or starting gear will be required, only, as in all other steam hammers, the control of the steam way must be entirely in the hands

of the hammer: man, or rather of his assistant, so as to be able to cause the hammer to strike a single gentle blow, or at the rate of three or four hundred per minute with extreme rapidity and power. The extent of the vibration of the cylinder is less than four degrees. In the diagram a spring is introduced, as in the original working model, in order to promote the return and fall of the hammer, but of course, on a large scale, the vacuum-piston would be the proper expedient.

Commerce.

WOOL.—Messrs. Ronald and Son, in their annual circular, state:—The imports of wool show a steady increase from year to year, those of 1864 being about thirty-one million pounds more than in the previous year, which increase consists chiefly of colonial wools. The exports, on the other hand, if compared with 1863, exhibit a falling off by about eight million pounds, owing to diminished shipments to America, caused by its almost prohibitory tariff; in fact, the decrease in exports to that quarter amounts to nine and a-half million pounds, but as opposed to this there is an increase in the exports to France, the total diminution is reduced to about eight million pounds. The quantity of wool left for home consumption is consequently very much more than in former years. From the Board of Trade returns we find that the exports of woollen manufactures have in the aggregate increased considerably, amounting for the eleven months ending 30th Nov., 1864, to £22,307,204, in place of £18,525,506 for the same period of the preceding year. Australian wools have this year arrived in larger quantity than ever, being 302,801 bales against 241,488 bales in 1863:—

IMPORTS AND EXPORTS OF COLONIAL, FOREIGN, AND BRITISH WOOL, FOR ELEVEN MONTHS:—

	COLONIAL. lbs.	FOREIGN. lbs.	
Imports, 1860	86,460,239	42,202,888	
" 1861	96,095,597	33,464,621	
" 1862	99,278,974	48,560,126	
" 1863	107,226,923	47,270,926	
" 1864	128,730,453	57,184,135	
	COLONIAL. lbs.	FOREIGN. lbs.	BRITISH. lbs.
Exports, 1860, 22,782,089 ...	4,128,869	10,997,181	
" 1861, 38,087,570 ...	6,580,625	14,501,006	
" 1862, 32,261,247 ...	10,106,645	9,537,266	
" 1863, 43,163,742 ...	12,179,788	7,956,463	
" 1864, 41,375,088 ...	5,794,840	7,377,769	

TEA SUPPLIES.—Messrs. Travers and Son, in their weekly Trade Circular, state that the Russian demand has been very much exaggerated, as during 1863 the shipments of tea to that empire only amounted to 1,280,788 lbs., but during the autumn of 1864, the readiest buyers of the new teas were the Russians, who were compelled to pay the high rates in order to get their purchases into the Baltic before winter began. With regard to the prospects of the tea trade during the present year, we may remark that the exports from China between June 1st and November 30th amount to 89,760,000 lbs., against 88,368,569 lbs., in the corresponding period last year; while the stock in the United Kingdom, in spite of a large and increasing home and export trade, continues as heavy as it was in the beginning of 1864. It seems probable, therefore, that the prices will decline still further. The reduction of the tea duty has already proved a great boon to the working classes, but it must not be supposed that they have yet reached one-fourth of their consuming power. While the middle and upper classes infuse 10 lbs. weight of tea per head throughout the year, the working man infuses less than three. When we consider that the slopes of the Himalayas alone

are officially reported as capable of producing ten times as much tea as we at present import from all tea growing countries put together and when we also bear in mind that Great Britain, Russia, and the United States are no longer the only tea-drinking countries out of Asia, but that all Continental Europe is gradually being weaned from the coffee-pot to the tea-pot, it may with confidence be asserted that the trade is in reality in its infancy,—that, large as our present consumption appears, it will be greatly increased in forthcoming years, while other nations who have as yet hardly begun to use tea will join in extending the demand, which can hardly exceed the supply.

Colonies.

THE CADIANGULLONG COPPER MINES.—Advice from the copper mines in New South Wales state that thirty tons of fine copper had been produced in October. The lodes continue of the same promising character, and the quantity of ore being raised is considerably on the increase. The fifth furnace has been completed, and a sixth is in course of erection. With these improved facilities, it is anticipated that there will be a large addition to the supply of copper monthly sent to market. It is also the intention of the directors to erect machinery for dressing the ore, which will further tend to increase the returns. The last parcel of copper sold by Messrs. Mort and Co., consisting of about ten tons, realised £92 5s. per ton.

SCHOOL OF ART FOR QUEENSLAND.—The sum available on public contribution of an equal amount is no less than £900. Upwards of £400 have been already subscribed; and, with the prospect of a substantial building, it can scarcely be doubted but that public confidence will be equal to a contribution of the remaining portion required to secure the whole of the parliamentary grant available.

COTTON AND ARROWROOT IN NEW SOUTH WALES.—Cotton and arrowroot have been grown by the Rev. Edward Holland, at Port Macquarie. Two bales of cotton, weighing altogether 319 lbs., were grown from Sea Island seed; it is considered by judges to be of very fair quality, being of a bright colour, rather strong in staple, and free from seed. Its value in Liverpool at the last quotations would be from 28d. to 30d. per lb. This is the largest quantity of cotton, the produce of the colony, that has yet arrived in the Sydney market. The arrowroot appears to be of very good quality, and to have been very carefully prepared. It was made by an experienced West Indian in Mr. Holland's employment. Mr. Holland states that he has about 400 lbs. of it, and that if a reasonable price were obtainable he could extend the production. It may possibly take some time to overcome the prejudice in favour of the imported article; but there seems no reason why the colonists should send to England for it if such good arrowroot can be made in the colony. At the recent show of the Agricultural Society a sample of sugar, also grown by Mr. Holland, at Port Macquarie, was exhibited, and attracted considerable notice; and the cultivation of sugar was strongly advocated by Mr. Holland, as one that would yield constant and healthy employment for thousands of old and young, while it would afford large profits to capitalists and cultivators who would take the matter up. Mr. Holland is entitled to much credit for the pains he has taken in testing the adaptability of this climate to the cultivation of the products of other countries, and also in communicating to the public the successful results of his experiments.

SILK IN THE CAPE COLONY.—The *Commercial Advertiser* states:—"A few days ago we paid a visit to the large collection of silkworms belonging to Mr. Wright, of the Royal Engineer Department, and were surprised to find that he had so large a number of worms, in all stages of their growth, some having but a few days previously emerged from their shell, while hundreds of others were forming cocoons of silk, and some had already finished

spinning, the produce of the cocoons having been wound off ready for making up into skeins. It is no exaggeration to say that Mr. Wright has hundreds of thousands of worms under his care. Some idea may be formed of their number and voracity from the fact that they consume daily two sacks of mulberry leaves. This number of worms are the produce of half-a-dozen female moths some two years ago, and we can but regard the success of this experiment of producing silk on a scale large enough for purposes of trade as highly satisfactory. The mulberry that grows wild in this country is ascertained to be the real China variety, and it is therefore the natural food of the silkworm. It is well known, and can be easily cultivated, and forms an excellent hedge. The first course is a mere trifle, the attention required can be given by a child, while the silk will always command £1 per pound in the market."

Notes.

SOUTHERN COUNTIES ASSOCIATION FOR THE ENCOURAGEMENT OF AGRICULTURE, ARTS, SCIENCE, MANUFACTURES, AND COMMERCE.—An Association under this head is now being formed, the objects of which are to promote by meetings in the counties of Hants, Berks, Oxford, Surrey, Sussex, and Kent* in succession,—1st, for the exhibition of stock and implements, or articles connected with the pursuits of any of the departments established by the Association; and 2ndly, for the reading of papers and discussions on subjects embraced within the scheme of the Association. The Association will be under the management of a council empowered to make bye-laws, offer prizes, nominate local or sub-committees, fix meetings, and do anything necessary to the carrying out of the objects of the Association; and the Council is to consist of a president, two vice-presidents for each county, an honorary secretary for each department, and 36 members, of whom an equal portion shall be chosen from each county by the members belonging to that county, or in default thereof, by the members in general at the annual meeting. An annual meeting and exhibition will be held in the months of May or June. Portions of the mornings or evenings of each day shall be given to the reading of papers and discussion. Each separate branch of the exhibition will be arranged and managed, under the control of the Council, by a sub-committee of the department to which it belongs. Other meetings may be fixed by the Council for the reading of papers and holding discussions. A department for each subject embraced by the Association is to be established, and the societies promoting these objects, for the purposes of the exhibition and meeting, will be amalgamated. Agriculture in all its branches, with its implements and machinery, will form the first department; natural history, local geology, botany, and horticulture, the second; the arts, manufactures, and commerce, as developed in these six counties, the third; local history and archaeology, the fourth; and the improvement of the dwellings and the general condition of the labouring classes, the fifth. Any other department may be added by the Council. Every subscriber of 10s. per annum shall be a member, and entitled to vote for the election of the Council. Every subscriber of £1 shall, in addition, be entitled to receive the reports and papers of the Association. Every subscriber of £2 per annum shall, in addition, be eligible for the office of president and vice-president. No subject or question of a political tendency shall be introduced at any meeting of the Association. Communications may be addressed to the Hon. and Rev. Samuel Best, Abbott's Ann, Andover;

or Thomas Pain, Esq., Ugford-cottage, Salisbury. The first general meeting of the members, for the election of the officers and Council, and other general business, will be held at Guildford, Tuesday, January 17th, at one o'clock. A large number of noblemen and gentlemen of influence, and residents in the several counties, have signified their adhesion to the Association.

MICHIGAN LAKE TUNNEL AT CHICAGO.—The most important event connected with the Water Works, and making a part of their history for the year, is the commencement of work on the tunnel, to be extended out under the bed of Lake Michigan two miles, so that the water will be drawn from the lake that distance from the shore. This project was fully set forth in the last report of the Board, and was adopted early last year, as that promising to secure most certainly, and with least expense to the city, its supply of water from a point in the lake where it will not be affected by the discharge from the river, or other impurities from the lake shore. During the summer, examinations were made along the whole line of the contemplated work, by boring at short intervals, to the depth proposed for the tunnel, to ascertain the character of the material through which it would pass, and various observations were made to test the quality of the water at the proposed outer end and inlet for the tunnel, and to ascertain also the distance from the shore to which the water of the river reached after certain most marked discharges of the river into the lake. From the borings it was found that the material through which the tunnel would be built was uniformly clay, and apparently of a firm and even character; and the observations concerning the effect of the river on the lake showed that, even when most marked, no trace of its influence could be detected much more than a mile and a quarter from the shore. The information obtained on these and various other points, satisfied the Board that the tunnel would accomplish the result sought for, and that the work was entirely practicable. The necessary drawings and specifications were prepared as speedily as practicable, and advertisements were issued in New York and Boston, as well as here, inviting proposals for the doing of the work. The bids were received and opened September 9th, 1863, most of the parties submitting proposals being present at the opening. The bid of Messrs. Dull and Gowen, of Harrisburg, Pa., being unconditional, and for the whole work, was accepted by the Board the day after the reception of the proposals, as the lowest and best bid. Soon after its acceptance, the Board made report of their doings to the Common Council, and requested to be authorised to proceed with the work, and to issue bonds to provide for its cost. The Council granted this desired authority by ordinance of October 5th, 1863. Subsequently to the execution of the contract, the Board desired to change the manner of constructing the land shaft, which was originally designed to be wholly of brick, and is so described in the specifications. The change consisted in substituting three cast iron cylinders, each ten feet long, essentially like the iron cylinders proposed for the outer lake shaft, in the place of the brickwork of the upper thirty feet of the shaft. This was done to facilitate the sinking of the shaft through the bed of quicksands overlying the clay, the distance through the quicksands to the clay being about twenty-four feet. The formal breaking of ground took place on March 17th last, and the work has been in progress since that time, with occasional interruptions. As was anticipated, a good deal of difficulty has been experienced by the contractors in working through the water and quicksands, but the difficulty has been much less with the iron cylinders than it would have been with brick work, and the clay having been reached, it may reasonably be hoped that there will not be serious trouble from this cause hereafter. Of course the work is not sufficiently advanced to enable the Board to form a conclusion as to what rate of progress may be looked for. The time fixed in the contract for the completion of the work is November 1st, 1865. Besides the

* At a meeting held at Basingstoke, December, 12th, 1864. Vincent Everaley in the chair, the County of Wilts was removed from the scheme as being included in the Bath and West of England Society.

change in the manner of constructing the land shaft, the Board have agreed with Messrs. Dull and Gowen to make certain changes in the outer crib, so that the crib will be stronger than as originally proposed, and so that solid masonry can be eventually substituted for the mass of loose stones with which the crib will be filled. The State Legislature had previously given the necessary authority for placing in Lake Michigan any piers to be found necessary for constructing and maintaining the tunnel, but, to avoid any question as to the right of the State to make such a grant, the sanction of the United States to the act of the State Legislature was obtained by act of Congress, passed January 16th, 1864. The tunnel is to commence at such point as may be selected by the Board of Public Works, on the lot now occupied by the pumping works of the city of Chicago, at the east end of Chicago-avenue, and on the shore of Lake Michigan; and to extend two miles out under the lake, in a straight line, at right angles to the general direction of the shore. The bottom of the inside surface of the east end of the tunnel will be sixty-six feet below the ordinary level of the lake, or sixty-four feet below what is usually known as "City Datum;" and the bottom surface will descend uniformly, at the rate of two feet per mile, to the west end of the tunnel. There are to be one land and two to four lake shafts; the land shaft at the west end, one lake shaft at the east end, and the remaining lake shaft or shafts at such intermediate points as shall be determined upon by the said Board, when the proper time for locating them shall arrive. The lake shafts are to consist of cast iron cylinders, and to be protected by hollow, pentagonal cribs. The tunnel is to be very nearly circular in form, and to have an interior width of five feet, and height of five feet and two inches.—*From Report of Chicago Board of Public Works.*

Announcements by the Council.

CANTOR LECTURES.

“ON THE REPRODUCTION OF NATURAL FORMS BY ART AND MANUFACTURE.” By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

Mr. Hawkins will resume his Course, on Monday Evenings, as follows:—

JAN. 23RD.—LECTURE IV.—On the fitness of designs, and their adaptation to the conditions of the materials in which they are to be produced. (Demonstrated by metal-work processes, sand-moulding, casting, and chasing).

JAN. 30TH.—LECTURE V.—On Ceramic Manufactures, with the Influence of the material on the design and its successful production—modern Terra Cotta, Della Robbia ware, Majolica, and Parian.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture. A set of tickets for this purpose has been sent to every member.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

JAN. 25.—“On the Best Mode of Protecting London from the Ravages of Fire.” By CHAS. F. T. YOUNG, Esq., C.E.

FEB. 1.—“On London Sewage, from the Agricultural Point of View.” By J. CHALMERS MORTON, Esq.

DWELLINGS OF THE LABOURING CLASSES.

In consequence of the unanimous recommendation of the Conference on this subject which was held in June last, the Council have appointed a Committee with the view of instituting an inquiry, to ascertain if anything can be done to remedy or to mitigate the evils arising from the want of proper Dwellings for the Labouring Classes.

The following is a list of the Committee:—

Acland, T. Dyke.	Holland, E., M.P.
Akroyd, E.	Holland, E. T.
Bass, Michael T., M.P.	Hoskyns, C. Wren.
Belper, Lord.	Lanckester, Dr.
Berners, Lord.	Lansdowne, Marquis of.
Best, The Hon. and Rev. S.	Lethely, Dr.
Blaime, D. Robertson.	Lichfield, Earl of.
Bosanquet, C. B. P.	Lumley, W. G.
Buccleuch, Duke of.	Malahide, Lord Talbot de.
Buckingham, Duke of.	Marsh, M. H., M.P.
Burnell, George R.	Maynard, H.
Chadwick, Edwin, C.B.	Mill, J. Stuart.
Chance, Robert L.	Morton, J. Chalmers.
Chester, Harry.	Redgrave, Samuel.
Cole, Henry, C.B.	Salisbury, Marquis of.
Cowper, Rt. Hon. W., M.P.	Shaftesbury, Earl of.
Denton, J. Bailey.	Shaw, Benjamin.
Dillon, John.	Shuttleworth, Sir J. Kay,
Ducie, Earl.	Bart.
Ebury, Lord.	Smith, Dr. Edward, F.R.S.
Farnall, H. B.	Smith, Professor Goldwin.
Fostescue, Earl.	Sopwith, Thomas, F.R.S.
Foster, P. Le Neve, Sec.	Stanley, Lord, M.P.
Society of Arts.	Toulon, Seymour.
Fawcett, Professor.	Twining, T.
Godwin, G.	Walker, G. H.
Graham, P.	Waterlow, Alderman.
Greenhill, Dr.	Wellington, Duke of.
Hamilton, Edward.	Williams, C. J.
Hare, Thomas.	Wilson, George F., F.R.S.
Harrowby, Earl of.	Ware, Martin, Secretary to
Hastings, G. W.	the Committee.
Hawes, Wm.	

To accomplish this object in the most satisfactory manner, it has been determined to divide the General Committee into Sub-Committees, to each of which distinct portions of the inquiry shall be assigned, so that the inquiry into each part of the subject may proceed simultaneously.

A Sub-Committee will undertake the inquiry—

1. Into the causes which appear to retard the erection of proper house accommodation, and the improvement of existing Houses for the use of the Working Classes, in London and other large towns.

2. Into the operation of Imperial and Local Taxation on such Dwellings.
3. Into the Laws relating to the Transfer of Real Property in small plots, and the conveyance of chambers or *suites* of rooms.
4. Into the operation of the destruction of Houses for Railways, and for other local improvements.
5. Into the desirability of facilitating the means of conveying labourers to and from their work by railways.
6. Into the pecuniary results of investments in Buildings for the Working Classes, either by Public Societies or by Building Societies.

A Second Sub-Committee will inquire—

1. Into the causes which retard the erection of Cottages in the rural districts.
2. Into the effect of facilitating the conveyance of small plots of ground for cottages and gardens, as well upon landlords as on workmen.
3. Into the effect of relieving—in the interest of the public only—certain classes of dwellings from all, or a portion of, local and imperial taxation.
4. Into the effect of extending the areas of local taxation, either to the union or the county.

A Third Sub-Committee will inquire—

1. Into the operation of the Laws of Settlement and Removal.
2. Into the advantages or otherwise likely to arise from the establishment of a National Poor Rate.
3. Into the provisions contained in various existing Acts of Parliament for granting Loans for the improvement of Estates, and whether such provisions cannot be applied to improvements of estates arising from building Cottages thereon; and if so, what special conditions should be imposed on grants to be applied to such purposes.
4. Whether the provisions of the Common Lodging House Act, the Health of Towns Acts, and other Statutes relating to Public Health, may not be advantageously extended.
5. And whether there are any other means by which the Legislature can promote the object in view.

Members of the Society interested in this subject are invited to communicate with the Secretary of the Society.

ART-WORKMANSHIP.

The following letter has been addressed to about forty of the principal City Companies:—

GENTLEMEN,

The Society of Arts has for a long period endeavoured to improve the artistic taste and skilful manipulation of the Art-Workman.

It has sought to accomplish this by exhibitions of their works, and by giving prizes for the best works executed from examples provided by the Society, and, in the case of wood-carving, from the original design of the workman.

Last year and this year, the prizes given by the Society have been on a much larger and more comprehensive scale than before, amounting last year to between £500 and £600; and the adjudication of the prizes has been kindly undertaken by gentlemen of acknowledged taste and high professional reputation.

The Council of the Society, satisfied that great good has been done by these efforts, and urged forward by the members of the Society, and by members of various trades requiring the aid of well-trained and skilful workmen, venture most respectfully to ask for the co-operation of the City Companies in promoting this practical mode of stimulating the energies and encouraging the self-education of the Art-Workman.

To this end the Council of the Society submit to the consideration of your honourable Court whether a sum of money might not be appropriated as prizes, say of £15, £10, and £5, for works to be executed by art-workmen in the branch of manufacture or of art represented by your guild; for, although your guild may not now be directly connected with the production of works of art, the Council venture to suggest that every corporation is interested in the general question of good taste, and in seeing the products of it when it meets together. In any case they think that models or drawings of some of the valuable works of art belonging to your worshipful Company might be offered for imitation, especially in the precious metals. I may add that any prizes that your Company may be pleased to offer now will not be required till about this time next year.

The Council, in order to afford your honourable Court an opportunity of appreciating what the Society of Arts is now doing, previously to your arriving at a decision on this subject, will be gratified if you can attend a meeting, at the Society's Rooms, on Tuesday, the 17th January, at four o'clock, when the works executed by art-workmen this year, in competition for the prizes offered by the Society, will be exhibited, and every information relating to this subject—in which the Society feels great interest, and to encourage which they desire your co-operation—will be afforded. I am directed to say that if the Master of your Company wish it, I have instructions to call on him and afford him full explanations.—I have the honour to be, Gentlemen, your obedient servant,

P. LE NEVE FOSTER, Secretary.

P.S.—Any member of your Court will be admitted upon giving his card, with the name of the Company of which he is a member written thereon.

To the Master, Wardens, and Court of Assistants,
of the Worshipful Company of —

Proceedings of the Society.

CANTOR LECTURES.

THIRD LECTURE.—MONDAY, JAN. 16.

Mr. HAWKINS commenced his lecture by drawing a parallel between the state of general education and the present state of art education. A few years ago the Society of Arts began their present system of examinations in general knowledge, in order to facilitate the education of the middle and industrial classes of society, but art education was still left in the same condition as that in which general education was placed a quarter of a century ago. Mr. Hawkins, therefore, suggested that the Society of Arts should do for art education what they had already done for the other branches of knowledge. The lecturer proceeded to speak of ornamental art as distinct from mere pictorial representation, and as connected with manufactures. He stated that the ornamentist required a more intimate knowledge of the structure of the forms of those animals which he intended to introduce into his designs, than the mere painter of pictures, who could always have a model before him and represent what he saw, whereas it was necessary that the ornamentist should possess the power of representing animal forms in any of the varied attitudes that he might desire without the presence of a living model. Mr. Hawkins pointed out the error that was made in supposing that the mere reproduction of natural forms is ornamentation, and said that the use that ought to be made of animals in ornament was to so adapt their attitudes that they shall fall into the lines of the design without violating nature. He referred to Mahomedan art (from which animal forms were excluded) as the perfection of the conventional treatment of the forms of vegetable life, and Indian and Chinese art as the perfection of ornamental combinations on which animal forms were introduced. The lecturer illustrated his

argument throughout with sketches on the black canvas, particularly of symbolic forms, the Nineveh bull, the Sphinx and Centaur, flying and aquatic dragons, &c.

SEVENTH ORDINARY MEETING.

Wednesday, January 18th, 1865; William Hawes, Esq., Chairman of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Beloe, Chas. H., 26, Bedford-place, Russell-square, W.C.
 Bishop, James, 176, Upper Thames-street, E.C.
 Bowring, John, 51, St. Mary-axe, E.C.
 Dean, John M., The Grove, Stratford, E.
 Gilson, John, 1, Stamford-terrace, Stamford-hill, N.
 How, Thomas, 29, Gloucester-place, Hyde-park, W.
 Hughes, Joseph, 37, Queen-street, Ratcliff, E.
 Lavey, Charles, 341, City-road, E.C.
 Parker, George Bass, 25, Grove-terrace, Highgate, N., and 4, King-street, Cheapside, E.C.
 Paty, General Sir George William, K.C.B., 24, Regent-street, S.W.
 Peard, Thomas, 159, High Holborn, W.C.
 Pendergast, John, 103, Adelaide-road, N.W.
 Pike, Fred., 44, Charing-cross, S.W., and Dulwich, S.E.
 Pitman, William, 210, Euston-road, N.W., and 88, Newgate-street, E.C.
 Plowden, Trevor Chichell, Oriental Club, S.W.
 Plucknett, George, 258, Gray's-inn-road, W.C.
 Pratt, Hodgson, 8, Lancaster-terrace, Regent's-pk., N.W.
 Rajlander, O. G., 129, Malden-road, N.W.
 Robinson, Thomas, 260, Gray's-inn road, W.C.
 Roebuck, William, 21, Ellington-st., Arundel-square, N.
 Sconce, Gideon C., 48, Lincoln's-inn-fields, W.C.
 Sexton, George, M.D., 63, Springfield-road, St. John's-wood, N.W.
 Sharp, Henry Locker, 15, Great Cumberland-street, W.
 Shaw, Maltman Wm., 24, Carlton-hill-villas, Camden-road, N.W.
 Stanton, John, M.D., 9, Montagu-square, W.
 States, William, 12, Prince's-street, Hanover-square, W.
 Stevens, Henry, M.D., 78, Grosvenor-street, W.
 Stewart, Donald, 7, Gloucester-terrace, Regent's-park, N.W.
 Stuart, Charles, Manor-house, Stepney-causeway, E.
 Taylor, John Henry, The Limes, Upper Holloway, N., and 15, South-street, Finsbury, E.C.
 Teape, Hannaniah, 37, Trinity-square, Tower-hill, E.C.
 Thomas, William, 20, Boltons, West Brompton, S.W.
 Thorold, Rev. Anthony Wilson, 16, Bedford-square, W.C.
 Vickers, Stanley, Hill House, Streatham-common, S.
 Waller, Edmund, 217, Brompton-road, S.W.
 West, William Nowell, 38, Montague-street, Russell-square, W.C.
 Whytock, Alexander, 9, George-street, Edinburgh.

AND AS HONORARY CORRESPONDING MEMBER.

Honeyman, Rev. D., D.C.L., Antigonish, Nova Scotia.

The following candidates were balloted for and duly elected members of the Society:—

Bayley, John C., 1, Park-place-villas, Malda-hill, W.
 Buxton, William, Lime-tree Lodge, Rotherhithe, S.E.
 Hancock, Henry J. B., Duke's-hill, Bagshot.
 Knight, John Peake, South Eastern Railway, London-Bridge, S.E.
 Lowe, John Stanley, 31, Cornmarket-street, Oxford.
 Melliss, George Whalley, 17, Talbot-terrace, Westbourne-park, W.
 Parnell, Hugh, M.A., 8, New-square, Lincoln's-inn, W.C.
 Strachan, Charles Henry, 51, King's-road, Camden-town, N.W.
 Vincent, Henry, 28, Mornington-crescent, N.W.

The following Institutions have been received into Union since the last announcement:—

Darwen, Mechanics' Institution.
 Redditch, Literary and Scientific Institute.

The Paper read was—

ON THE BEST MODE OF APPLYING POWER TO PROPEL TRAINS ON THE METROPOLITAN AND OTHER RAILWAY LINES HAVING FREQUENT STATIONS, AND IN TERMINAL STATIONS.

By PETER W. BARLOW, Esq., F.R.S.

My attention was first especially directed to the subject of the motive power on railways in the year 1844, when I was instructed by the directors of the South-Eastern Railway to report on the applicability of the atmospheric system to the Tunbridge Wells branch of the South-Eastern Railway, and my investigation, containing some experiments on the Tyler-hill incline of the Whitstable Railway, was laid before the Institution of Civil Engineers in 1845.

In the year 1848, on the opening of the North-Kent Railway, the locomotive superintendent reported to me that a much greater consumption of coke occurred than with similar trains on the main line, which was supposed to arise from the smaller radii of the curves and steeper gradients.

The stations being more frequent on this line, it was necessary, in order to understand the cause of this loss, to distinguish what portion of the total power was required to put the trains in motion as distinguished from that employed in traction, and I calculated the acceleration of trains with varying tractive power, which was compared with the observed acceleration of locomotive trains on the South-Eastern and Great-Western Railways, and with the experiments made by Mr. Stephenson on the Atmospheric Railway at Dalky.

It is sufficient for the present purpose to say that, with what due allowance for the loss of tractive force with increase of velocity, the experiments fully confirmed the theoretical calculations, and left no doubt of the practical accuracy of the formula. (See Appendix.)

In the progress of these experiments on locomotives, I remarked the serious loss of time which arose in getting the train into speed; and it will be seen by referring to the tables that on the South-Eastern Railway, at that time, one and a half to two miles was generally required to get the train into full speed, and, on the Great-Western, between three and four miles; and it became apparent, by testing the rate of acceleration due to the tractive power of the North-Kent engines, that it was impossible to make the journey (stopping at every station) in the time required, even if the trains had no friction or incline to contend with.

The only remedy was engines of greater tractive power and weight, and these have been adopted to such an extent, to meet all cases, that, under favourable circumstances, a momentum and velocity is given to the train in 150 yards that would be sufficient to take it half a mile on the level if the engine was detached; and having recently observed this fact, it occurred to me that in working metropolitan lines, with frequent stations, sufficient power might be given at the station by stationary power to propel the train, without the aid of a locomotive, to the next station; and having, upon careful consideration, arrived at an opinion that such a mode of working will give a greater average velocity, and be apparently superior in other respects to the use of locomotives in such cases, I have been desirous to lay my investigation of the subject before this Society, as a matter deserving of discussion, from its important effect on the capability of metropolitan railways to relieve street traffic.

In the ordinary duty of locomotives, as employed upon

the great systems of railways, the distance between the stations or points of stoppage is such that the great and important duty of the engine is to maintain the requisite speed after that speed has been acquired; and one of the first facts which an inquiry into the subject cannot fail to establish is, that the locomotive engine is admirably adapted for this purpose; and, as regards the fuel expended for a given amount of work, it is one of the most economical forms of engine in use.

This result will appear, whether we take the work performed by an express engine in a fast train, or a heavy goods engine drawing a slow train; and in either case it results that, provided the distance between the stations is large, so that the engine can work for a considerable time, exercising its power at a fair working speed, the economical working of locomotive engines, comparing the work done with the fuel consumed, become manifest.

When, however, the duty to be performed is that of working a line in which the stations are very close together, and the stoppages frequent, it then results that all, or nearly all, the work of the engine is expended in acquiring the travelling speed; and that, in fact, it has not ceased to accelerate its speed when it becomes necessary to shut off the steam and apply the brakes, so as to stop at the next station. In fact, the same engine which in long stages would make an average speed of 35 or 40 miles per hour, is incapable, with frequent stations, of making an average speed of 13 or 14 miles, even with a greatly reduced load.

In this condition of things, which is in fact the condition of metropolitan railways, a new set of circumstances has to be met, and the question arises whether, where these circumstances exist, stationary power, when applied in a manner strictly adapted to the case, is not more economical—capable of greater speed—and in all respects more suitable to the convenience and exigencies of the traffic than locomotive power?

In terminal stations the use of stationary power will add much to the simplicity of working. At present, as the locomotive arrives in front of the train, it is made prisoner until the train is removed. It has then to go to another part of the station to be turned on to take in coke and water, and then comes back again to the train it has to take out. These frequent operations not only wear out the road and points and crossings very rapidly, but cause constant stoppages to trains arriving to enter the station. To avoid a portion of this difficulty, the locomotives are sometimes run tender first, a mode of working which amounts to an admission of imperfection, and appears to foreshadow a change in the present system, particularly as the more the traffic increases the more these imperfections will be felt. When the stations are near together the time required to acquire the speed is so important an element that greater tractive power is requisite to enable a reasonable average speed to be maintained; and the power of the engine is governed by the power requisite to put the train into motion. Thus the actual power exerted to propel trains of forty tons every five minutes each way on a railway similar to the Metropolitan, of three and a half miles in length, at the velocity now adopted, would not, allowing one-third 214 horses, lost power, and 16lbs. per ton traction, exceed to obtain which at least ten locomotives, capable of exerting in the aggregate a power of 2,200 horses, are required in consequence of the combined losses from the extra weight to be conveyed, the power to overcome the inertia, and, thirdly, from the engine being restricted from making a fair working speed, these losses being in addition to that of the engine itself from friction, &c.

Seeing that it is necessary to use such powerful engines to passenger trains where the stoppages are frequent, it follows that the weight of the engine becomes large in proportion to the weight of the train, and therefore, if that weight can be dispensed with, much less power will suffice to give the same amount of speed, or, with the same amount of power applied, a much greater speed will be obtained.

In like manner if the weight of the engine is dispensed with the train can be brought to rest in less time by means of the brake; and coupling this with the increased rapidity with which the speed at starting can be acquired, it follows that dispensing with the weight of the engine would be of very great advantage in the case of stopping trains. In order to show the disadvantages under which locomotives act when stations are frequent, a comparison is here made of the speed which will be obtained by a locomotive weighing 40 tons, having an effective tractive power of 4,000 lbs., with a stationary engine of the same power, and one of 8,000 lbs. tractive power, the stations being assumed to be 1,000 yards apart, and the railway in the first place level, the second on a gradient of 1 in 200, and the third on a gradient of 1 in 100.

The rate of acceleration is correctly represented by an incline obtained by dividing the total weight conveyed by the effective power, and will be understood by the diagrams on the next page, in which the line — — — — — represents the incline due to the locomotive; the line that due to the stationary power with four thousand lbs. tractive force; and the line — — — — — that due to eight thousand lbs. tractive force. The following tables show the relative inclines and velocities:—

No. 1.—RAILWAY LEVEL.

POWER EMPLOYED.	Incline representing rate of acceleration.	Distance the power acts.	Time of passing 1,000 yards.	Average velocity per hour.
		Yards.	Min. Sec.	Miles.
Locomotive train tractive power 4,000 lbs.	1 in 56	794	1 57	17½
Stationary engine tractive power 4,000 lbs.	1 in 25	455	1 28	23
Stationary engine tractive power 4,000 lbs.	1 in 12	216	1 16	27

No. 2.—GRADIENT 1 IN 200.

POWER EMPLOYED.	Incline representing rate of acceleration.	Distance the power acts.	Time of passing 1,000 yards.	Average velocity per hour.
		Yards.	Min. Sec.	Miles.
Locomotive train tractive power 4,000 lbs.	1 in 78	863	2 12	15½
Stationary engine tractive power 4,000 lbs.	1 in 28½	523	1 31	22½
Stationary engine tractive power 8,000 lbs.	1 in 13	223	1 18	26

No. 3.—GRADIENT 1 IN 100.

POWER EMPLOYED.	Incline representing rate of acceleration.	Distance the power acts.	Time of passing 1,000 yards.	Average velocity per hour.
		Yards.	Min. Sec.	Miles.
Locomotive train tractive power 4,000 lbs.	1 in 125	905	2 37	13
Stationary engine tractive power 4,000 lbs.	1 in 33	405	1 34	21½
Stationary engine tractive power 8,000 lbs.	1 in 13·4	242	1 20	25½

Fig. 4 is given to represent the relative velocities of the locomotive and stationary engines.

FIG. 1.—RAILWAY LEVEL.

FIG. 2.—GRADIENT 1 IN 200.

FIG. 3.—GRADIENT 1 IN 100.

FIG. 1.

FIG. 2.

FIG. 3.

	Miles per hour.		Miles per hour.		Miles per hour.
Locomotive power	Average velocity	17½	15½	13	
Stationary equal power	"	23	22½	21½	
Stationary double power — — —	"	27	26	25½	

It will be seen, by reference to the table, that in the No. 1, viz., level, the velocity has been increased from 17½ to 27 miles per hour, and the time saved 41 seconds. In No. 2 gradient, 1 in 200, the velocity has been increased from 15½ miles to 26 miles per hour, and the time saved 54 seconds; and in No. 3 gradient, 1 in 100, the velocity has been increased from 13 to 25½ miles per hour, and the time saved 1 minute 17 seconds. It will also be observed that the tractive force of the stationary engine, when double that of the locomotive, is only employed less than one-third of the distance, and therefore greater velocity has been obtained with less expenditure of power; and hence arises an important advantage in favour of stationary power, as proposed to be employed, as not only less actual power is required, but, a much smaller length only of propelling power being necessary, the expense of power and liability to derangement hitherto experienced in stationary power will, in a great degree, be avoided. The obtaining increased velocity with less power is not only an anomaly, but its correctness will readily be proved, and will be illustrated by the experiment of applying stationary power, by means of a weight sufficient to

propel a carriage with a small acceleration. By applying four times that weight for a quarter the distance the acceleration is very rapid, and the average velocity will be increased with the same expenditure of power, and in degree depending upon the ratio of the accelerating power to the load in the two cases. I am, therefore, able to claim for stationary power, when stations are frequent, the advantage of superior speed, an advantage which has been found to be of importance to the success of railways generally, and their influence in the districts through which they pass, and one which there is no reason to doubt will equally influence the development of the traffic of metropolitan railways, if not to a greater degree, because the saving of time is at present less decidedly in favour of railways. If stations were a little more frequent than they are, a good cab would still remain the quickest mode of travelling; and it is so now, unless the railway runs direct to the point to which a passenger is destined. Speed is also important, from enabling more frequent trains, and therefore a larger amount of traffic, to be carried on one line of railway.

FIG. 4.—DIAGRAM OF RELATIVE VELOCITIES.

The economy arising from stationary power is not here advanced as of the usual importance in railways, perfection of working being rather the point to be aimed at, as it would pay itself from the development of traffic in a metropolitan railway, even at greater outlay and cost, but as the economy claimed is so great as nine-tenths, with equal velocities, it is necessary to explain how this extraordinary difference arises. That the loss from the use of locomotives on metropolitan lines is fully nine-tenths of the power employed, is pretty evident, because the total duty performed in propelling trains of 40 tons every five minutes, equal to forty tons 84 miles per hour, or 200 tons 16½ miles per hour, is not greater than one of the locomotives employed (which are in fact equal in tractive power to goods engines), would perform on a main line as a fair day's work, and the cause of this loss it is not difficult to comprehend. As before stated, it arises from three causes:—1st. The increased weight of the train from the addition of the weight of the engine. 2nd. The loss in overcoming the inertia of the train and consequent application of the brake; and 3rd. The large proportion of the time the locomotive is under steam, as compared with that on which it is employed advantageously in traction. The degree of economy from the weight of the locomotive being saved of course depends on the relation of its weight to that of the train. On railways worked by stationary engines, the weight and friction of the rope, from its great length, generally exceeds the loss from the locomotives; but in metropolitan railways the locomotives are required to be of such weight as nearly to equal that of the train, and, therefore, half is directly lost from this cause.

The loss from overcoming the inertia of the train will be arrived at by comparing the power employed in each case. If the double power represented by the line - - - on the diagram is continued for 100 yards, the velocity on the level will be 27 miles per hour; and if the train is allowed to run by its own momentum it will be 18½ miles at the point where the brake is applied, producing an average of 20 miles, a velocity considerably exceeding the locomotive. The power exerted will be as 200 to 799, or as 1 to 4 nearly. This explains a loss of ¾ of the locomotive power, the remainder making it ¼, being due to the locomotive not being an accumulating power, or, in other words, the power exerted in the two cases is as 1 to 4, while the engine power necessarily employed is 1 to 10, from the engine being restrained from making a fair working speed.

The case here assumed for illustration is that of the railway being level. On gradients exceeding 1 in 200 it will be necessary to have a greater velocity than is now made by locomotives to give sufficient momentum, and thus a direct comparison cannot be made; in fact, the advantage claimed for stationary power, is the means of giving increased speed combined with great economy rather than that of excessive economy with the same speed. There is no doubt, however, that a saving could be made of two-thirds of the present cost, still giving a large improvement in speed.

Frequent trains are, in the opinion of experienced persons, both in this country and in America, necessary to develop the omnibus traffic; and there is no reason why, with stationary power, from the improved velocity, they could not be made to run every three or four minutes, allowing sufficient time for one train to leave its station before the following train was allowed to start. This could not be done without locomotives treble in number to the stationary engines, even if there was required to be one stationary engine at every station. Another source of economy will arise by stationary power, from less destruction of the permanent way, and, in underground railways, from a less dimension of tunnel being required when a single line is used.

The two important points of comparison, viz., speed and economy, are here shown to be in favour of stationary

engines, and as the avoidance of the locomotive would be a benefit to the travelling public, particularly in tunnels, and equally so to the residents on the line, by reducing the noise and vibration, and is also decidedly conducive to safety, stationary engines would appear to be the superior mode of working railways with frequent stations unless there arise practical objections to balance these advantages. Two objections have been suggested; one, that the rate of acceleration will be so rapid as to be unpleasant to passengers; and the second, that in the event of a train, from any cause, being stopped between stations, it would be left in a helpless condition for want of locomotive power.

With reference to the first objection, it is only necessary to observe that the rate of getting into motion will not produce a greater velocity than $1\frac{1}{2}$ miles per hour at the end of 50 feet, which is not so great a rate of acceleration as arises in a carriage propelled by horses; in fact, if the rate of acceleration which now arises with locomotives in descending gradients was given to trains on the level and in ascending, a very important saving of time would be made, and no objection could arise on this point. With reference to a train being stopped between stations, it must be assumed that the momentum given to the train would be such that considerable brake power would be always required to stop it at the next station. The distance the train is to be propelled by momentum is much less than is done every day by detached carriages on the principal lines of railway; in fact, every locomotive train is propelled the latter part of its journey by momentum; and in the case of express trains more than a mile is required to stop, with the assistance of the brakes. The Greenwich and Blackwall Railways were worked into London by momentum nearly as far as is here proposed, and were never known to fail as long as the engine power acted properly. The cause of interruption to the traffic by an accident to the locomotive itself will be avoided, and that which now occasionally arises from the repair and renewal of the permanent way will be much reduced. On a metropolitan line devoted exclusively to passenger traffic, there are no level crossings, and the public are entirely excluded, so that the stoppage of the train, except from accidents, will be very rare, and no train would leave one station until the line was signalled clear to the next. A pilot locomotive, in case of accidents, would be used as at present, as the mode of applying the stationary power will not prevent the occasional use of locomotives.

ON THE MODE OF APPLYING THE STATIONARY POWER.

The mode of applying stationary power here suggested differs from that hitherto employed, inasmuch as it is not connected from station to station, or connected through several stations, like the Blackwall system, but each has a propelling power independent of the other, although the power may be derived at several stations from one engine. It also differs in that the power is used accumulatively, and thus a smaller power of engine is required.

I will now observe that the result of the experiments on the Whitstable Railway, previously referred to, and the examination generally of the subject of motive power, led me to recommend the Directors of the South Eastern Railway to substitute locomotive, and abandon the stationary engines on that line; and the alteration was attended with satisfactory results, not because there was any serious difficulty in the rope system, except its great weight and length, but because one locomotive was made to do the work of all the stationary engines, and a greater average speed was obtained. One of these ropes was 1 mile 70 chains in length; and on the Blackwall Railway the rope was above three miles in length to carry passenger traffic. Great mechanical skill and good workmanship is indicated by the fact that such a piece of machinery could be kept in order for any length of time, because the actual weight put in motion, and inertia to be overcome, in addition to the train, was much greater than that of a locomotive, besides the friction of 800 sheaves. These cases, however, prove that no practical difficulty or

liability to derangement is likely to arise in the use of a rope for 160 or 200 yards only, as is now proposed; and it may be here remarked that although ropes have been superseded by locomotives in many cases, yet that still a large amount of traffic is carried on by ropes, and in one important instance, viz., Glasgow, the locomotives have been again abandoned for the rope on an incline of 1 in 43 for one mile fourteen chains used for passenger traffic.

The mode which first occurred to me of applying the stationary power for the present purpose, was, by Sir W. Armstrong's hydraulic principle, to give motion to a rope, which system has the advantage that one engine can be made to do the work of several stations by a water main laid along the line. Another form of propeller, very simple in its action, but requiring an engine at each station, is the descent of a weight raised by a small engine constantly at work.

The power expressed by a weight of forty tons raised thirty feet every two minutes and a half would propel a train of forty tons more than one mile and a quarter on the level before it came to rest; and a stationary engine of forty-eight-horse actual power, allowing one-third loss, would be sufficient to run forty-ton trains every five minutes each way, allowing for the loss from friction and the power required to bring the weight to a state of rest, which latter loss would amount to ten per cent. of the power. The cost of working such an engine, including repairs, would not amount to £2 10s. per day, so that the cost per train per mile would be under 2d. The trains may also be propelled on the atmospheric principle, either by the old plan, of a pipe, or Mr. Rammell's plan, of a small tunnel; and as the power is required only for a short distance, there will not arise the difficulty from friction and leakage which has hitherto been experienced in these modes of traction.

In another form of propeller suggested, which is specially adapted to frequent trains, the accumulation of power is made in the boiler. Driving wheels and cylinders, similar to a locomotive, are used to propel a rope for the required distance. The total weight of moving machinery will not in this case, including the rope, exceed four tons. A duplicate of every part, including the boilers, would be provided, and as there is an interval of eight hours' rest in each day, sufficient to replace any part which might be out of order, I submit that such a piece of machinery may be considered nearly safe from derangement. A propeller of either kind, it is suggested, could be used advantageously on railways worked by locomotives, for the purpose of starting trains from stations situated at the foot of inclines, where now locomotives, although generally master of their work, frequently fail in surmounting the incline, thus leading to loss of time and danger.

In conclusion I will observe that it is difficult for the author to describe a new suggestion without a bias in its favour, but I have endeavoured to lay the comparative merits of stationary and locomotive power fairly before the meeting. The subject is so important in its influence on the value and extension of metropolitan railways, that I offer it for discussion without venturing to give a decided opinion of my own, until I hear the views of those eminent engineers who have devoted their attention to the subject of motive power, and which views, I hope, will be expressed on this occasion.

APPENDIX.

The formula used in calculating the acceleration is:—

$$v = 2\sqrt{\frac{T}{P \pm \frac{T}{I} - \frac{T}{2240f}} \cdot 8.16\frac{1}{2}}$$

I being the inclination of the railway.

P the tractive power.

T weight of train in lbs.

S length of the plane.

f friction of the train per ton.

The velocity given to a train of 40 tons by 4,000lbs. falling 600 feet or 8,000lbs. falling 300 feet, the friction being 15lbs., will be—

$$2 \sqrt{\frac{(8000 - 600) \cdot 300 \times 16\frac{1}{2}}{89,800}} = 27 \text{ miles per hour.}$$

The power exerted will be for five-minute trains.

8,000lbs. falling 300 feet in two minutes and a half.

$$\text{or } \frac{8000 \times 300}{2\frac{1}{2}} = 940,000 \text{ lbs. in one minute.}$$

$$\frac{940,000}{38,000} = 24\frac{1}{2} \text{ loco. power} \times 5 = 142.5.$$

add one-half..... 71.25.

213.75.

DISCUSSION.

MR. BARLOW said, before he described the experiments he had to bring before the meeting he wished to add a few remarks to what he had written. In suggesting a substitute for the locomotive he had no intention to undervalue the qualities of that engine; on the contrary, he regarded it as the master-piece of mechanical engineering, and the results it produced were perfectly astonishing, as also was the amount of duty it was capable of performing; he entertained the highest respect for those men whose talent and thorough knowledge of the subject had brought that machine to its present state of perfection. He appeared before them, therefore, not as an opponent of the locomotive, but rather as a great admirer of it; and he merely suggested that this noble machine, when employed as the motive power on a railway of short length and frequent stations, was not able to exercise more than about one-tenth of its power. What he (Mr. Barlow) submitted was, that under certain circumstances stationary power might be employed with advantage; and because it had failed under other circumstances there was no proof that it would not succeed under those which had now arisen. The alteration he suggested in the application of stationary power, consisted in this—that instead of applying that power between station and station, he applied it for such a distance that the momentum, or *vis viva* of the train, was brought into play, and this was as much a force as the force of steam, and could be depended upon as well as any other force. He proposed to apply the power of the rope for such a portion of the distance that the momentum of the train would carry it with perfect certainty to the next station. The advantage of applying it for a portion of the distance and allowing it to act in that way, arose from a particular law of accelerating forces, from which it resulted that a greater tractive force applied for a portion of the distance would accumulate a momentum that would give greater speed than a smaller tractive force applied for the whole distance, the actual power being the same in each case, because the greater force acts for a proportionately less distance. Mr. Barlow then proceeded to illustrate this principle by a model of a carriage propelled by means of a weight suspended. By applying four times the tractive force for a quarter of the distance only, he obtained greater velocity over the whole distance than by applying the tractive force for the whole distance. The difficulty with regard to stationary power hitherto had been the great length and weight of the ropes; but with short ropes he submitted they could manage the machinery perfectly well. Another experiment was shown, to prove that by reducing the weight of the carriage by about one quarter, double the velocity was obtained with the same amount of motive power. This was brought forward to show that where

the duty of the locomotive engine was an accelerating and not a tractive power, by relieving the train of the weight of the engine, they did more than save the mere weight of the engine, and therefore produced a greater economy on lines where there were frequent stations than on lines where the duty of the engine was entirely of a tractive character. The principle of accelerating force was further illustrated by the motion of a ball rolled down first a gentle incline, and then down a steep incline, and so carried by its momentum up a gradient to the same level as before, but with a greater velocity. This explained why a greater velocity was obtained when the same power was employed over a shorter distance.

MR. IMRAY said that as, in the course of several conversations with Mr. Barlow, that gentleman had asked him to look into his calculations, he would now venture to state his opinion as to their accuracy, and to explain as briefly as possible the view he took of the principle on which Mr. Barlow had based them. It might, at first sight, be difficult to understand how by a temporary impulse given to a train, instead of a continuous traction being applied to it, there could be an economy of power for a given speed, or an increase of speed for a given power. The illustration which Mr. Barlow had given of a ball rolling down one incline and thereby acquiring momentum sufficient to carry it up another incline, appeared to him to embody the whole principle under discussion, and he would endeavour to apply, as clearly and briefly as he could, the same principle to the case of a railway train running on a level. From the experiments made by Pambour, it appeared that the resistance to the motion of a train amounted on the average to 10 lbs. per ton or $\frac{1}{10}$ th of the weight in motion. The experiments conducted by the British Association seemed to show that this resistance amounted to about 8 lbs. per ton, or $\frac{1}{10}$ th of the weight. Since those experiments were made, great improvements had been effected, both in the carriages and in the permanent way; but, without laying any stress on that circumstance, he would merely take the mean of the above figures, and state the resistance as about 9 lbs. per ton, or about $\frac{1}{10}$ th. It might, in fact, be taken that a train in motion was subject to a constant retarding force equivalent to that which it would, without friction, encounter in running up an incline of 1 in 250. If then a train were started with the velocity which it would acquire in descending such an incline, it would, leaving friction out of account, ascend that incline before its velocity entirely vanished. Assuming that the stations were one mile apart, and that it would be desirable for the train to retain a certain amount of speed, say seven or eight miles per hour, to be overcome by the brakes on reaching the farther station, the length of the incline might be taken at 6,000 feet. The gradient being 1 in 250, the total height of the incline measured from base to summit would thus be 24 feet. In other words, a train descending through 24 feet of vertical height would attain sufficient velocity to carry it one mile on the level, retaining at the end of the mile a velocity to be arrested by the application of the brakes. The power necessary to effect this upon a train weighing 40 tons or 89,600 lbs., would be $89,600 \times 24 = 2,150,400$ foot lbs., or equivalent to the work of a 65-horse engine during one minute. As to the mode of giving this velocity, he would not trouble the meeting with any remarks, for that was rather a question of practical engineering than one of figures, to which he now wished to confine himself. Let it, however, be assumed, for illustration, that the velocity was given to the train by causing it to descend an incline of 100 yards, or 300 feet, in length. The total descent being 24 feet vertical, this would give an incline of 1 in $12\frac{1}{2}$, or a tractive force of 721 lbs. for a 40-ton train; and whether the velocity were given by the descent of such an incline, by the application of rope traction, or by any other means, the power expended and the result produced would be precisely the

same. As to the objection which would, no doubt, be raised to Mr. Barlow's system, because the velocity would be too rapid, or rather too suddenly imparted, he was of opinion that it was quite groundless. The rate at which a passenger was put in motion in a cab or omnibus considerably exceeded that contemplated in the case in question. Any one that had taken a trip on the "Montagne Russe," where the descent was something like 1 in 4, must have experienced a start something like three times as sudden as it would be in the case under consideration, and he (Mr. Murray) would observe, for his own part, that the sensation on the "Montagne Russe" at starting was rather pleasant than otherwise. To quote another instance, that of the Cycloidal Railway, where the passenger was inverted in his progress towards the terminus, the descent at starting was something like 1 in 2, and certainly no unpleasant shock was occasioned at the start in this apparently perilous journey. He regretted having occupied the time of the meeting so long with dry figures, but he trusted that he had succeeded in confirming the truth of Mr. Barlow's calculations, and he had only to thank his hearers for the patient attention with which they had listened to his observations.

Mr. ZERAH COLBURN remarked that he had no doubt the system now brought forward possessed advantages in respect of the working of underground railways, especially in avoiding the nuisance arising from the vapours of combustion from the locomotive engine, and it would save much of the great wear and tear of permanent way caused by the locomotive itself; but, it seemed to him, when they had got so far all the advantages of the proposed system were at an end. He did not know whether Mr. Barlow had proposed to adapt the railway to the system or the system to existing railways. If it was proposed to adapt this system to the Metropolitan Railway, he would apply it to the case of the King's-cross and Gower-street section on that line. The distance between those two stations was 50 chains, or five-eighths of a mile, with a gradient of 1 in 100, or a total rise of 33 feet. A train to arrive at Gower-street from King's-cross must, upon the proposed system, start with a velocity at least equal to that which a body would acquire in falling from a height of 33 feet. This would be expended in overcoming gravity only, but they had also to overcome the friction and the resistance of the atmosphere. Instead of the sum of these resistances being only 15 lbs. to the ton he believed the experiments made on the Metropolitan Railway showed that the resistance at the moderate speed employed on that line was something like 25 lbs. per ton. He would take $22\frac{1}{2}$ lbs. per ton as a convenient figure. Thus, in order to get over the gravity and other resistances over that distance, the train must start at a velocity equal to that of a body falling from twice 33 feet, or 66 feet. But it would not do to run into Gower-street station by the simple exhaustion of the momentum of the train. It should have a terminal velocity of at least 15 miles an hour to be extinguished by the brakes. In order to do that, the falling body assumed would have to fall from an additional height of $7\frac{1}{2}$ feet; therefore the train must be started with a velocity equal to that of a body falling $73\frac{1}{2}$ feet in order to arrive at the intended point on that gradient. The velocity required would be something like 70 feet per second, 66 feet per second being equal to 45 miles an hour, and that would hardly be a proper rate at which to start in order to get over the short distance between those two stations. The question was whether it would be safe or prudent to start at that speed. Would the carriages bear the great strain necessary to produce it? Would they keep the rails? Then, again, the whole of the power applied to the train was to be expended within a distance of 300 feet. A train of 40 tons weight was assumed, but this he believed was but about half the maximum weight of the trains on the Metropolitan railway, irrespective of the engine. To give a train of even 40 tons a velocity of 66 feet per second,

starting up this incline, would require the exertion of about 6,300,000 foot lbs. of mechanical power, which had to be put into the train in a distance of only 300 feet, so that the constant force must be equal to 21,000 lbs., or nearly three times the maximum power of the engines now employed on the Metropolitan railway.

Mr. BARLOW said the speaker was arguing upon entirely wrong premises.

Mr. COLBURN inquired within what distance the power was to be applied?

Mr. BARLOW replied 242 yards.

Mr. COLBURN added, that brought the rate down in the proportion of 726 to 300; but his argument was merely to illustrate the case of 300 feet, which had been mentioned. It would be a most rapid acceleration of speed even if the distance were twice and a-half what he had first supposed to be intended. The power was applied very suddenly, and the starting must be at the rate of 45 miles an hour to do the distance between those two stations, and he did not think either the carriages or the line could stand that, even if it were not productive of great inconvenience to the passengers themselves. Besides, he had heard no mode suggested by which that velocity could be obtained within so short a distance, nor did he yet see how the power was to be connected with the train without causing violent shocks. On these points he should be happy to hear Mr. Barlow's explanations.

Mr. SEYMOUR TEULON would feel obliged if Mr. Barlow would explain the manner in which he proposed to connect the rope with the train for so short a distance, and also how he proposed to disconnect it.

Mr. BARLOW replied that the length of the rope depended upon the gradient to be worked. If the gradient were 1 in 100 it would require a greater length of rope, and the steeper the gradient the more advantageous was this system. The mode of detachment from the rope was precisely that adopted on railways at the present time, viz., by means of a pin.

Mr. T. MARR JOHNSON thought Mr. Barlow had lost sight of the extreme inconvenience of fixed plant. It was the great difficulty which attached to the atmospheric and the pneumatic systems. Let them imagine the inconvenience of a break-down of the engine. Mr. Barlow said there were eight hours of the twenty-four left for repairs: but on the Metropolitan Railway there were only four hours. In case of a break-down Mr. Barlow had said there would be a pilot engine to get over the temporary difficulty, but this could not work the traffic. If there occurred a break-down of the engine or rope, the chances were it would take a week to repair; and even with plant in duplicate it might take a day. If the traffic of the Metropolitan line were stopped for a day, 30,000 people would be prevented from travelling over it, which would ultimately have considerable effect upon the dividends of the shareholders. It was absolutely necessary, not only that the trains should run with great frequency, but that they should also run with the greatest certainty, or travellers would be deterred from using the line. Another consideration with respect to the adoption of this system to the Metropolitan line was the fact that that line was worked in connection with the Great Western and the Great Northern railways. The trains of those lines could not possibly be worked partly by locomotive and partly by rope traction. Locomotives must work the long traffic, and might therefore as well bring the train on to Farringdon-street. The truth was, moreover, that in order to get over the difficulty of a break-down of the machinery, it would be necessary to keep eight or ten locomotives in stock.

Mr. BURNETT said that the tractive force required to propel the trains on the Metropolitan Railway up the incline of 1 in 100 between King's cross and Gower-street was 6,900 lbs. for a train of 70 tons. Deducting the weight of the locomotive, which might be assumed as

one-third that of the whole train, the force required would then be two-thirds of the 6,900 lbs.

Mr. THOS. WEBSTER, F.R.S., said the subject before them was one of much interest, and they must all feel indebted to Mr. Barlow for having brought forward a proposal having for its object to obviate what was, no doubt, a great difficulty in the working of a railway like the Metropolitan. All engineers, he believed, had come to the opinion that it was desirable, if possible, that some other system of working these lines should be adopted. The locomotive engine was no doubt one of the most perfect machines ever invented, and the amount of work it was capable of doing was astonishing; but when they considered it was adapted, in the first instance, to the working of long lines, carrying enormous weights, with few stoppages as compared with the metropolitan system, which involved a great number of stoppages, the time he thought had arrived when they should endeavour to provide some other means of propulsion on the metropolitan system, which was being so rapidly extended, particularly as in long tunnels the foul air from the locomotive was a serious nuisance. At the same time it could not be denied that, as was stated by Mr. Johnson, the difficulties in introducing either the rope, the atmospheric, or the pneumatic system on such a line as the Metropolitan were very great; but he thought it was no answer to the proposition before them, to say there were difficulties in the way of its adoption. They must look at the whole question, because he thought there was a strong feeling on the part of the public, and of many engineers, that the whole system of working these metropolitan lines must be reconsidered. If that were so, although they must admire the great skill with which the Metropolitan railway was worked, he thought a proposition coming from a man of Mr. Barlow's practical experience ought to be received with the greatest consideration. The atmospheric principle, judging from former experiences of it, he apprehended was quite out of the question, and the pneumatic system was as yet almost untried. The question was a most important one, and Mr. Barlow having brought it before them—not as an amateur—not as a mere adventurer, but as one who had had a vast amount of experience in the working of railways, he hoped it would receive, as it deserved to do, most careful attention.

Mr. CHAS. VIGORLES, F.R.S., believed that theoretically and mathematically Mr. Barlow's calculations were accurate. He would say with regard to what had fallen from Mr. Johnson, that the difficulties attending the break down of the stationary machinery were not much to be apprehended. Both the atmospheric and rope systems had worked for many years without any failures from the breaking down of the engine. He thought as far as the ordinary practical working of a line was concerned, the stability of fixed engines as they were now made might be entirely depended upon, particularly if duplicates were supplied where necessary; but with these admissions he was not prepared to say that the system of working metropolitan lines by stationary rather than by locomotive power, had arrived at that degree of ripeness that they could adopt it. The atmospheric system was worked for many years with some failures, but the truth was it did not pay from a variety of causes. He was not aware of the precise reason why the rope on the Blackwall line was abandoned; but he could quite understand that on a line perfectly open a comparison between the locomotive system and stationary engines would be very much in favour of the former. But, now they had railways under ground, there were a variety of circumstances, chemical, sanitary, and otherwise, which altered the nature of the case very materially. He quite agreed with Mr. Webster that the time had come when they should seriously discuss the desirability of working these metropolitan lines by other means than the locomotives now in use. He was not prepared to say Mr. Barlow's system was the best. He thought that gentle-

man had underrated the power of resistance, though perhaps Mr. Colburn had overrated it, and therefore he thought the motive power calculated on by Mr. Barlow was too low; but in his opinion sufficient had been said to show that the stationary system was worthy of trial. He apprehended it would be difficult to get that trial, owing to the great expense it would involve, and he did not think an experiment on a small scale would be successful. With all Mr. Barlow's mathematical talent he thought the system was hardly ripe enough to be brought into practical operation, though he felt indebted to him for having brought the subject forward.

Dr. BACHHOFFNER remarked that the sanitary question, in connection with underground railways, owing to the nuisance in tunnels arising from the vapours of combustion from the locomotive, was a very important one. He expressed his surprise that during the discussion no allusion had been made to the description of locomotive which he understood had been modified by Mr. Fowler to such an extent, that it gave out no vapour whatever during the passage through a tunnel. In fact, it was a gigantic tea-urn, with a heater inside of sufficient capacity to keep up the steam, while passing through a tunnel, without any products of combustion escaping from the furnace. He was not aware whether that kind of engine was generally employed on the Metropolitan Railway. As far as he gathered of the mode of attachment of the train, it appeared to him that both in the attachment to, and detachment from, the rope, a very sudden jerk to the passengers must be occasioned.

Mr. S. TAYLOR said when he asked the question as to the mode of attaching the carriages to the rope, he did so as one materially affecting every system of rope traction where the rope was not continued from one terminus of the line to the other. He believed the rope on the Blackwall line was abandoned in consequence of its connection with other lines, worked by locomotives, rendering that system inconvenient. He fully agreed with the opinions expressed by Mr. Webster and other speakers that, where a railway consisted mainly of tunnels some other mode of traction than the locomotive should, if possible, be adopted; but he doubted whether in practice it would be desirable to have a series of either weights or stationary engines, because there would be a difficulty of detachment as the carriages arrived at each station. It was stated in the paper that with frequent stations on a metropolitan line, worked by locomotives, a journey could be accomplished quicker in a cab with a good horse than by the railway, and he should be glad to hear whether, under the system proposed, the journey by railway would be expedited. He apprehended that unless the train was started at greater speed by this system than by the locomotive they would be in the same position in that respect as they were now. With regard to the jerk at starting, they all knew that if the driver turned on the steam too quickly at first an effect not pleasant to the passengers was produced. Although a system of rope traction might be a very good one where the stations were close together, and where all the carriages were attached to the same power, so that they could not have one carriage overtaking another, they must remember that on all the metropolitan lines they had to provide for the arrival of locomotives from long distances on other lines; because he did not understand that the rope system was proposed to be adopted throughout the country. He had much desired to call the attention of Mr. Barlow to difficulties which at present he had not shown how he could overcome.

Mr. R. K. BOWLEY begged to remind the meeting that Rammell's Pneumatic Tube had been at work regularly for a long time at the Crystal Palace without interruption or accident. He would not give any opinion on its merits, but would merely state this fact for the information of the meeting.

Mr. CHUBB, having been connected with the management of a metropolitan line for the last ten years, would

truck him that the suggestions of Mr. Barlow led to a return to a system which he regarded as exploded. The rope traction on the Metropolitan Railway was an utter failure. Mr. Robert Stephenson stuck to his child till he could endure no longer. It was not only ruinous to traffic, but the cost to work that traffic with any regularity was enormous. It was not abandoned, however, on account of the difficulty of junction of lines, for it was quite practicable to effect this change over the rope at the points of junction. The rope, however, was perpetually breaking, and horses had to be used to bring it home after the difficulty of getting the broken ends had been accomplished. The expense of the rope system on that line had caused an addition to the capital of the company of not less than £100,000; and, after every possible material for the rope had been tried, all of which failed, it was happily abandoned for the system of locomotive traction. He considered that motive power ought to accompany the train, and believed the right thing to do was to deal with the difficulty itself, and endeavour to modify its construction to meet the requirements of the new system of traction that had been commenced, but he earnestly recommended not to return to the rope system.

Mr. Johnson thought the alleged deterioration of the atmosphere in the tunnels of the Metropolitan railway was much exaggerated. He referred to the fact of the enormous traffic which was daily carried on that line, and that it was not viewed with disfavour by the public. He remarked that if the engines which ran from the Metropolitan in connection with the Metropolitan were as good as the vapours of combustion as were those employed by the company, there would be no cause of complaint on that account. With reference to the alleged deterioration of the atmosphere in the tunnel stations, he would state that the system was introduced to bring down the good air from the surface and drive off the bad air from below; but after having been a little time in operation the officials begged to have it removed, as it was questioned whether the atmosphere brought down was not worse than that which existed in the tunnel.

Mr. Joseph Smith remarked that the fact was lost sight of that the journey from Bishop's-road to Farringham was accomplished in eighteen minutes, which was a very short time to pass in even a confined atmosphere. He should be sorry to be left in one of the tunnels of the Metropolitan line as he had often been on the Metropolitan, through the failure of the rope system.

The Chairman said it now became his duty to ask the meeting to accede to a vote of thanks to Mr. Barlow for his paper with which he had favoured them on a subject which was exceedingly important, not only to the public, but to all who travelled by railways, and especially on the metropolitan lines. It appeared that Mr. Barlow had brought before them a system, novel in many respects, though not essentially so. Mr. Barlow told them that on a line where the stations were frequent, they might with advantage employ the system of propulsion that was not available where the stations were more distant apart, and where the expense of the rope required would be exceedingly great. He maintained that, by employing fixed engines and rope for short distances, there would be a saving of engine power, and reduced expenditure in the general working of the line. He had shown that by taking advantage of accumulation, an economy of power and an increase of speed could be obtained, but he had omitted to notice the consideration of securing a much purer atmosphere in the tunnel. They must recollect that, in the case of lines for which the sanction of Parliament had been obtained, tunnels of greater length than they had on the Metropolitan would occur. It might be the case on the line from Victoria-street, to the Thames embankment, to Blackfriars, and also

on the proposed East London line, of which the Thames tunnel was to form a portion, and these being at much greater depth from the surface rendered the question of purity of atmosphere a still more important one. It was one of those engineering problems which should meet with full and careful consideration. It was satisfactory to find the calculations of Mr. Barlow supported by two able mathematicians, Mr. Imray and Mr. Vignoles. They were told that a great objection to fixed as compared with locomotive plant was the liability of derangement in the machinery, but this fear was originally expressed with regard to steamers, and yet those who had taken long sea voyages must have been struck with the undisturbed regularity with which the engines of steam vessels were worked almost without cessation for weeks together, which was sufficient, he thought, to dissipate all fears in connection with derangement of machinery. With regard to casualties, it should not be forgotten that it was proposed to have duplicate engines and therefore the chances of a serious break down in working this system were very trifling. He apprehended the purpose of this discussion was to ascertain the real merits of this system, for it must be remembered that we had to deal with what might be termed an entirely new class of railways, and therefore some improvement in the present mode of working seemed to be required. He confessed he hoped this was only one of many discussions which they would have in this room by which they might find a better mode of travelling underground than any hitherto adopted. Mr. Johnson argued from the large number of persons who travelled on the Metropolitan railway, that the system was as good as it could be, but if a better system were introduced he (the Chairman) contended more people might be induced to use the line. He concluded by moving a vote of thanks to Mr. Barlow for his paper, which was carried unanimously.

Mr. BARLOW, in acknowledging the compliment, said he would endeavour to answer the objections that had been brought against this system of propulsion. With reference to the Metropolitan Railway, he had said very little about that line in particular, but he had said he thought locomotives were generally very cruelly treated on lines with frequent stations, and on the Metropolitan line that cruelty was carried to the greatest extent, inasmuch as the locomotive was prevented from breathing whilst going through a tunnel, in order that the passengers themselves might be able to breathe. With regard to the figures given by Mr. Colburn about traction, he thought that gentlemen must have mixed up those figures with something in which he had been engaged on the other side of the Atlantic, as they had nothing in this country in the way of traction that agreed with his statements. With respect to what had fallen from Mr. Chubb relative to the system of rope traction formerly employed on the Blackwall line, it was no argument that because a thing had failed under certain conditions, it should not succeed under entirely different conditions. He (Mr. Barlow) had had very considerable experience in rope traction, and he was acquainted with all the difficulties connected with it. He was aware of the loss of mechanical power which was occasioned by the rope; but in the case of the Blackwall railway the great wonder was that it ever worked at all. It was a rope more than three miles long; and the difficulty of working a rope increased by more than the square of the length; so that it was no argument to say that because a rope of three miles failed, therefore a rope of three hundred yards could not succeed. With regard to the starting of the train, it had been objected that under the rope system there would be an unpleasant jerk, but this was not so much the case as under the present system, for with locomotives the couplings of the trains were frequently slackened when it was standing at a station, and the result was, when they put on the steam each carriage received a jerk at starting. He had been assured by Sir William Armstrong and other eminent practical men

which is not mentioned in this subject, that under this system a train would be started more gently than by a locomotive. The rate of speed at which it was proposed that the train should be started, was not necessarily higher than under the present system with a locomotive in a descending gradient. Moreover, if by the rope system they could make the train start and traveling as good as the treadmill at present, they would effect a material improvement. Besides, when it was considered that under the plan of propulsion trains could be run every three minutes they would not have such heavy trains to deal with as at present. On the subject of rope traction he would say further, he believed he was the first to advocate it in the Transport branch, and the example was followed in several other lines, including the Glasgow; but, in the latter instance, they were obliged to come back to the rope again; and for a distance of nearly a mile and a quarter a large passenger traffic was carried on by rope traction at the present time, and hence it could not be contended that any practical difficulty would arise with a time of 10, parts. Objections had been made to the rope system on the ground that it interfered with junctions; but the proposed mode of acquiring the rope traction for short distances entirely obviated this difficulty.

LOUIS INTERNATIONAL EXHIBITION, 1865.

Austria is making strenuous efforts to be well represented at the Vienna Exhibition, and it is to be hoped that the new commercial treaty which is now being negotiated with that empire will tend to a largely extended trade on both sides, when the existing fetters to commerce are removed. Austrian manufacturers did exceedingly well at the London International Exhibition in 1862, for besides gaining great honour, extensive sales were effected. Already it is said that Chevalier de Wernsdorff and Co., the celebrated workers in metal, will have a very fine display, with photographs of their works; and that Sencaut, of Prague, will send works in the precious metals. The porcelain by Fischer, which attracted so much notice in 1862, will be well represented. C. Krinning, of Vienna, will exhibit papier-mache furniture, in addition to objects in carton pierre, and fancy articles in wood. Messrs. Thonet Brothers exhibit bent wood furniture, for which they received a medal in 1862. M. Klein will send a magnificent collection of leather work, rivaling the one exhibited under the western dome in 1862. Meerschmann pipes and amber carvings will be shown, and there will also be a good collection from Austria of musical instruments, glass, clocks, oil paintings, photographs, and photographic apparatus, wines, and agricultural produce.

NORTH LONDON WORKING CLASSES INDUSTRIAL EXHIBITION.

The distribution of prizes awarded to the successful exhibitors at this Exhibition, held at the Agricultural Hall, Islington, took place on Monday evening, the 16th inst., at Exeter Hall. The Right Hon. the Earl of Shaftesbury, B.G., occupied the chair. A tonic solo choir, under the direction of Mr. Sari, sang several pieces of sacred music.

The meeting was briefly addressed by Mr. T. B. SHYFFER, Mr. SAMUEL MOWLEY, and Deputy-Judge PAYNE.

The list of successful exhibitors, with the names of the prize volume or article awarded to them, was then read, and the recipients, passing along the front of the platform, received from the hands of the Chairman the prizes they had gained.

The Earl of SHAFTESBURY said, in reference to the prizes, that never were rewards more honourably won. The working men had come forward generally to show what their class was capable of—what high aspirations and great powers they possessed, if only opportunities were afforded for their development. Such manifestations would not only be of benefit to the working classes them-

selves, but also of great and lasting benefit to the whole of the British empire. On behalf of the public, he would say that the public came forward to thank the working men in the same spirit in which they had contributed to the happiness of the whole British people. A remarkable feature of the Exhibition, and of that which preceded it, was the large proportion of works wrought by men not producing articles in their own department of industry—persons of different capacities had produced results of a character totally different to the trade in which they were engaged. The conclusion he drew from the Exhibition showed the necessity of a variety of occupations, and the earnest desire and craving for mental recreation amongst the great working class. Let the evening of the working man be devoted to the exercise of his genius, and to everything which could improve him morally and raise him in the social and political scale. He regretted to hear it suggested, with some degree of anxiety, that in all future Exhibitions of this kind—and he trusted they would be many—all exhibitors should be confined to the particular department of industry in which they were daily engaged. This would be undesirable. The object of such exhibitions was social rather than financial, and moral rather than commercial, for it was to hold out a healthy, joyous, and noble recreation to the working classes—to break and embellish the monotony of toil—to give a free safety-valve to genius and taste, and to that which, if not rightly inhaled, would be hurtfully indulged, namely, the power of the imagination. Such exhibitions tended to improve the conditions of social life, give dignity to domestic life, and throw over home all the allurements possible—to induce working men to give up the habits by which so many were degraded, and by the cultivation of their genius and the exercise of the affections, to make the family-hearth happy.

Mr. W. H. BOOKER (Assistant-Judge) proposed, and Mr. HARVEY seconded, a vote of thanks to the noble chairman, which was carried by acclamation.

PROTECTION TO INVENTORS IN INDUSTRIAL EXHIBITIONS.

On Tuesday, the 17th inst., a deputation on this subject was received by the Right Hon. M. Gibson, President of the Board of Trade. The request for an interview originally came from the committee of the West London, late Borough of Marylebone, Working Men's Industrial Exhibition; but, at their invitation, gentlemen connected with other similar exhibitions joined the deputation. Among those present were—Mr. E. M. Morrell, secretary to the West London Exhibition; Mr. Murphy, South London Exhibition; Mr. Raley, one of the honorary secretaries to the North London Exhibition; Mr. G. J. Knight, East London Exhibition; Mr. Christie, secretary to an Exhibition to be opened at Birmingham in August; the Rev. Eardley Wilmot, Mr. J. A. Nicholas, Mr. Peter Graham, &c.

Mr. Harvey Lewis, M.P., introduced the deputation.

Mr. MORRELL said there had hitherto been no system of communication between different districts with respect to these industrial exhibitions, but he now found that in every district the same difficulty had been experienced as that which the promoters of the West London Exhibition had to contend with. They were asked at the very outset whether they could afford protection to inventors who might exhibit, but who were too poor to obtain a patent, and who, by exhibiting without that security, might find themselves robbed of the fruits of their ingenuity and labour. Of course they were most desirous of affording such protection on the simple ground of justice, as well as expediency, for they soon found that unless such protection was given, the most valuable inventions of working men would be entirely withheld. The subject had been so strongly brought before them at many meetings, that they felt compelled to move in the matter, and, as a result

of their exertions, the Right Hon. Mr. Cowper, First Commissioner of Works, and Sir Roundell Palmer had both taken the subject up. It was, indeed, by the recommendation of the Attorney-General that they waited upon the right hon. gentleman in his official capacity, to ask him to introduce a short bill into Parliament for the purpose. The Attorney-General had stated his willingness to assist in the preparation of such a bill, and to take charge of it if it had the sanction of the Government. He urged upon the right hon. gentleman that there could be little difficulty in acceding to this request. That protection had been accorded to the inventors who exhibited at the Great Exhibitions of 1851 and 1862, and surely there could be no objection to do the same for the industrial exhibitions that were now springing up all over the country. He did not apprehend that on public grounds there would be any objection to such a measure, and he was sure that it would bring out hundreds of working class exhibitors who would otherwise withhold their inventions.

Mr. CHRISTIE, of Birmingham, Mr. MURPHY, of the South London Exhibition, and other gentlemen urged the importance of the measure.

Mr. NICHOLAY expressed his confident expectation that the Government would accede to the request of the deputation, and give to the poorer classes of inventors the same protection as they had given to wealthy inventors at the Great Exhibitions.

Mr. M. GIBSON said that if he understood the deputation clearly their immediate object was to get some bill brought in which would prevent any working man exhibiting at those exhibitions being prejudiced by such exhibition, or deprived of the fruits of his toil and ingenuity. That he understood to be their immediate object, and it was a very simple one. But there was one point to consider. How would they define which of these exhibitions was to have the benefit of the protection they asked for? In the case of the Exhibition of 1862, and the act they referred to, the matter was very simple, because that Exhibition was under the control of a special commission, and could, therefore, be specifically referred to. The difficulty in this case would be to find some title which was sufficiently general to cover the whole ground, and at the same time not go beyond the real object aimed at. He would be most happy to give the matter his best consideration, and should the Government sanction it, he had no doubt the Attorney-General would give his assistance, and take charge of any bill that might be introduced.

Mr. PETER GRAHAM suggested that a certificate from the Board of Trade would be a sufficient warrant for putting the provision of a general act in operation.

Fine Arts.

A MEDALLION of the Poet Laureate is now being published by Mr. Moxon, the publisher, which may possibly run through as many copies as the poems, that are perhaps scarcely more the exponents of the great poet's mind than is this medallion the reflex of his mind-undoubted features. The likeness is more striking than ordinary medallion-likenesses are, not only from the extreme accuracy with which the work is executed, but on account of this medallion (unlike most medallions) being taken in "three-quarters" instead of in "profile." There is, moreover, great "relief" gained by the employment of a concave ground, which not only negatives the possibility of these cast-shadows that disfigure most medallions (and give them the appearance of "a split-jowl" adapted by its cut-surface to a flat ground), but, at the same time, allows of a very considerable amount of side light, much more than is obtainable in profile medallions. It is intended that this likeness of Tennyson be produced at a very reasonable price, both in electro-bronze and in plaster

of Paris, and Mr. Woolner, the sculptor, and friend of Tennyson, has entrusted the entire management of this novel undertaking to the judgment of Mr. Moxon.

Commerce.

TEA SUPPLIES.—The following is from Messrs. Lloyd, Matheson and Co.'s annual statement:—The total imports to the United Kingdom amount to 122,600,000 lbs., against 136,000,000 lbs. in 1863. The total deliveries are 116,100,000 lbs., against 112,100,000 lbs., of which the home consumption is 88,200,000 lbs., against 85,000,000 lbs.; and the foreign export is 27,900,000 lbs., against 27,100,000 lbs. in 1863. The total stock in the United Kingdom on 31st December was estimated at 95,200,000 lbs., against 88,700,000 lbs. in 1863. The imports to Liverpool, direct from China and Japan, for 1864 are only 1,600,000 lbs. It is gratifying to observe a steady increase in the home consumption, which, though perhaps not fully up to the sanguine expectations of some, is fully 10 million lbs. increase on the figures before the reduction of the duty to 1s. per lb. The foreign export also appears steadily on the increase, at least as regards the continent of Europe; for notwithstanding the much diminished sendings to America during last year, the total exceeds the figures of the preceding year. With all the increase, however, the total deliveries do not come up to the liberal supplies which have reached this country from all quarters. From China and Japan we have received 116 million lbs., while India has sent about three million lbs.; and these, with occasional supplies from America and other countries, bring the excess of imports over deliveries to quite six million lbs. It is now evident that the reduction of duty has had the effect of stimulating the consumption of good to fine grades in each description of tea. These grades throughout the year have not been oversupplied; and, generally speaking, teas with quality have been readily saleable on arrival, not always at prices remunerative to importers, but at rates which were not materially below the average prices of similar grades in former years. We may here remark that while the demand has been stimulated for the finer qualities, the production in China appears to have deteriorated. The proximity to the producing districts at Hankow has evidently caused a rapid and careless preparation of the blackish leaf teas, but from one cause or another the quality of most of last year's, and so far of this, shows a decided falling off; there is a want of ripeness and evenness of quality in the chops, and the leaf is ragged and badly picked. The Foochow teas are not so much fallen off, as this season's fine show a decided improvement in real quality over last, if we except the Packin sorts; but the lower grades of the first crop are decidedly inferior. What is most to be regretted in connection with this depreciation in quality is, that buyers in China appear, in the majority of cases, to have paid for these teas as if they had been really fine, hence, both last year and this, differences of 4d. and 6d. per lb. were not unfrequent, not arising from a depreciation in the home market, but solely from the mistaken view of the quality abroad—as if tea was bought by its class, instead of by its intrinsic quality.

INDIAN AND JAPAN TEAS.—Messrs. Arthur Capel and Co., in their circular, state:—"Indian teas continue to be in great favour with the trade, owing to the general inferiority of the China crops; and the fine, strong, pungent kinds have sold dearer than ever; whilst the common, weak, and sour kinds have been generally difficult of sale, not being good enough for the purposes of admixture, for which they are mostly used. It is quite evident that if proper care in the cultivation and curing of Indian tea is taken, the result will prove a great success to all interested, as it only requires the superior strength and quality to be maintained to insure a ready sale at remunerative prices. Japan teas, as long as the demand

from America lasted, sold very readily at full prices, but they do not meet with favour from the home trade; and since the export to America has ceased they have been very difficult of sale. We fear that unless they can be made to assimilate more to China teas, either black or green, they will be always uncertain of sale, as they are entirely dependent on the American demand, which in the present position of affairs is liable to great fluctuations. The coloured kinds early in the year realised extreme prices."

THE EARTHENWARE TRADE WITH THE UNITED STATES.—Mr. T. H. Masters, of Liverpool, states that the annexed report shows at a glance how the earthenware trade with the United States has been going on during the war there, compared with the preceding years 1859 and 1860, which represent the usual extent of exports in ordinary times. The excessive falling off in 1861 may be ascribed to the ample stocks held by merchants and dealers at the beginning of that year (the first of the war) as compared with the demand which was looked for during the remainder of it, and also to the financial confusion which was expected to arise immediately upon the commencement of hostilities between the North and South. The exports of last year figure very satisfactorily when it is borne in mind that American importers have been surrounded by every species of impediment. The uncertainty which hung over the presidential election materially checked shipments during the latter part of the year, but recent advices indicate the prospect of a fair amount of business during 1865, unless some unforeseen events occur to prevent it. The following is a comparative statement of exports of earthenware from Liverpool to the six principal ports of the United States during the past six years:—

	1859.	1860.	1861.	1862.	1863.	1864.
To	Pkgs.	Pkgs.	Pkgs.	Pkgs.	Pkgs.	Pkgs.
New York...	43,317	43,920	15,649	30,495	33,434	37,143
Philadelphia...	13,390	13,780	5,089	10,762	10,364	12,147
Boston	16,599	18,955	7,024	8,747	10,283	12,560
Baltimore	2,194	2,107	340	869	243	587
Charleston	3,020	2,188	158
New Orleans	15,811	14,510	1,494	...	771	594
Totals...	94,231	95,460	29,754	50,873	55,085	63,021

In January, 1859, exchange at New York for bankers' bills on London was 106, and the Bank of England minimum was 2½ per cent. In the last week of 1864, exchange at New York for bank bills on London was 238.

TELEGRAPHIC EXTENSION AND REFORM.—Very great progress has of late been made in this important matter on the continent. The French Government has just placed the electro-semaphoric posts on the coast in connection with the general telegraphic system, so that messages may now be despatched and received at these outposts in the same manner as in the towns. The *Moniteur* has just published a complete list of these semaphores and of the more important places situated within the vicinity of each. Another very important announcement has just appeared in the same journal, containing the results of recent conventions made between France and foreign governments. According to the new arrangements the cost of a message between any of the offices of France and the Papal States is now 5 francs for twenty words, and half that sum for each additional ten words; between France and Prussia, east of the Weiser and Werra, 4 francs and 2 francs; between France and the Rhenish Provinces, and also between the former and Baden, 3 francs and 1½ franc. The importance of these conventions will be best understood by a few instances. A message between Paris and Rome will cost 5 francs instead of 13fr. 50c.; one between Paris and Cologne, 3 francs instead of 7fr. 50c.; between Paris and Berlin, 4 francs instead of 12 francs; between Marseilles and Dantzic, 4 francs instead of 15 francs; between Bordeaux and Memel, 4 francs in place of 18 francs; and between Toulouse and Carlsruhe, 3 instead of 9 francs.

THE COFFEE TRADE.—Messrs. Truman and Rouse, in their circular, state the stock of coffee in the principal entrepôts in Europe and Great Britain, on the 30th November, was 53,170 tons against 59,750 and 49,930 in 1863 and 1862. The deliveries in Holland continue satisfactory, being for the past year 890,400 bags against 725,700 in 1863, and the consumption in Europe generally appears to be fully up to that of last year. Looking forward to the prospects of coffee in 1865, there is every reason to anticipate a steady trade, and the continuance of remunerative prices to the planters in Ceylon and Madras, although, regarding the fact that both these countries will yield a considerably greater supply, it would be scarcely safe to reckon on so high a range of quotations as those of 1864. The shortness of the Java crop will, however, help us, as the demand for clean coffee on the Continent is evidently increasing. As respects Brazil the prospects are not so encouraging; the new crop will undoubtedly be large, and unless the consumption in America increases, the supply will probably be found somewhat too heavy for the European markets. The home consumption in Great Britain last year was but 16,530 tons, being 670 tons below the average of the previous two years. The increased use of coffee does not keep pace with that of tea in England.

CEYLON COFFEE PRODUCTION.—The following returns of the Ceylon Coffee Crops are extracted from the *Colombo Observer*:—Although the crop for season 1863-4 was very much smaller than that of 1862-3, yet, with that exception, it was the largest known:—

Total Crops of Coffee in Ceylon to the end of the Season (30th September) in the last Five Years.

YEARS.	PLANTATION.	NATIVE.	TOTAL.
	Cwts.	Cwts.	Cwts.
1860	472,618	180,241	652,859
1861	468,987	136,190	605,177
1862	414,298	170,824	585,122
1863	582,528	204,973	787,501
1864	516,962	137,949	654,911
Total for Five Years	2,483,293	810,177	3,293,470

The whole crop may now be said practically to have been shipped to London . . . This is rather a change since 1859-60, when out of a crop of 632,000 cwts., 130,000 went to countries other than England . . . If the figures received from Java and Brazil can be depended on, the out-turn of crop 1863-4 in the three great coffee countries of the world is as follows:—

	1863-4.
Brazils	2,800,000 cwts.
Java	795,000 "
Ceylon	654,000 "

Total

4,249,000 cwts.
Coffee cultivation is rapidly extending in Ceylon . . . As a probable out-turn of 900,000 cwts. of coffee is admitted for the season 1864-5, going on all former experience it seems pretty certain that the annual million will be made up or exceeded for the next five years. Indeed, it would not be extravagant to anticipate an export of two millions in 1870.

WINES.—Messrs. M. Clark and Sons, in their Annual Circular, state that the trade in wines and spirits, which has gradually progressed since the reduction of duty, has made a most marked and decided step in the past year, and while the imports have been somewhat excessive, and leave a heavy stock on hand at the present time, still the home consumption shows so great an increase as to justify the conclusion that the bonded stock is but little above the requirements of dealers, and may speedily be reduced, if importations are moderate, by the deliveries during the next two months. The past year has been the largest in imports and deliveries that we have yet had, and compared with the average rate of delivery under the

old scale of duties, the home consumption of wine shows an increase of fully 66 per cent. This increase is the more remarkable, as it has been maintained throughout the year, in the face of monetary pressure and commercial disaster, added to the fact that prices of several descriptions of wines have ranged considerably higher than formerly.

Colonies.

SUGAR IN QUEENSLAND.—A very excellent sample of sugar has been shown, produced at the plantation of the Hon. Lorys Hope Cleveland. It is a portion of three tons of dry sugar and fifteen hundredweight of molasses, the produce of less than one acre of purple cane. Some inquiries have been made respecting the market value of this class of sugar, which is variously estimated at from £38 to £41 per ton. Mr. Strachan, the manager of the plantation, states that the canes from which it has been produced are the first that have been fully ripened, and that have had a fair trial given them since the formation of the plantation, and that he anticipates a much larger yield from future crops, as he intends to plough much deeper. He also states that at a small additional expense he believes that the sugar can be further refined, and rendered much more valuable. It is very gratifying to see so good a result of the work at the Cleveland station, and is a subject for much congratulation to Capt. Hope. It is also a matter of congratulation to the entire colony, as it must establish, even in the mind of the most sceptical, the sugar-growing capabilities of Queensland.

RAILWAYS IN NEW SOUTH WALES.—Tenders have been called for the Great Southern Extension, which will carry the railway into the town of Goulburn. The length of the line will be twenty-six miles twenty-seven chains, and it is to be let in one contract. There will be a number of heavy cuttings, but the most formidable works will be the bridges across the numerous rivers and creeks. Close to Goulburn there is to be a tubular girder bridge, over the Mulwaree Ponds, with twelve openings of sixty feet. It is not decided whether the piers are to be of stone or brick; prices for both kinds of work are to be given, and that which is found the most economical will be adopted. The line will twice cross the Wollondilly River; the bridge at the first crossing will have seven openings of sixty feet, and one of 130 feet; that at the second crossing will have six openings of sixty feet, and one of 130 feet. At Barber's Creek there will be a bridge with five openings of sixty feet; that at Box's Creek will have two openings of sixty feet. Excepting that at the Mulwaree Ponds, all of these bridges will have single-web iron girders; the piers to be of stone or brick as may be found most economical. Over several other creeks there will be large viaducts, mostly of timber. The ballasting and the permanent way will be included in the contract, for the performance of which three years will be given.

ALPACAS FOR NEW ZEALAND.—The *Wellington Independent*, of 29th Sept., says—"It is understood that his honour the Superintendent has succeeded in purchasing for this province ten alpacas, eight females and two males, and that they may shortly be expected from Sydney by one of the S. R. M. Company's steamers. This will be a great boon to the province, and as the climate and nature of the country are said to be peculiarly adapted for alpacas, we have no doubt they will thrive well, and that in the course of a few years the wool of the alpaca will form a considerable item in our exports."

Obituary.

It has been remarked that the past year was a fatal one for artists and men of science on the Continent; certainly

the list of the departed is long and melancholy. France has lost from the ranks of art the following eminent painters:—Alaux, member of the Institute, and formerly Director of the French School at Rome; Hippolyte Flandrin; Du Bufe, the elder; Allard, assassinated by one of his models at Rome; Ménissier, killed by a fall from the scaffold on which he was working in the church of Saules; Roehn, Mathieu Rivoulon, Pottin, Barbier, Besson, and Leopold Lobin, director of important stained glass works at Tours; the sculptors, Louis Brian, Aristide Husson, a pupil of David d'Angers, and author of a large amount of busts and decorative sculpture; Christophe Féatin, a clever modeller of animals; and Justin; the architect, Lusson, formerly engaged on public works in Paris, who has left his collection of drawings and plans to the Museum of Mans; Ménager, who won the Grand Prize of Rome at the early age of 18, and executed many public works; Azémar, the designer of some fine mansions in Paris; Boullé, of Rennes; Querrey, of Moulins; Segrétain, the restorer of many fine churches in the Department of the Deux-Sèvres; Pellegrini, of Chambéry, who built the baths and casino of Aix, and whose death is said to have been hastened by the vexation caused by the loss of all his plans, drawings, and sketches, in the fire that consumed the theatre of Chambéry; Jules Gagniet, a well-known illustrator; and the engravers, Achille Lefèvre, who exhibited great talent in reproducing the works of Raphael and Coreggio, one of his last productions being an engraving of the "Antiope," ordered for the chalcographic establishment attached to the Louvre; Deschamps, of Marseilles; and Godard, engraver on wood, and conservator of the Museum at Alençon. The French Institut, besides Alaux and Flandrin, mentioned above, lost Ampère, Clapeyron, A. Garnier, Hase, Arnaud-Lefebvre, and Admiral Du Petit Thouars. Amongst savans may be mentioned, Professor A. Cochet, chemist; A. Digot, author of the "Archæological History of Lorraine," twice crowned by the Academy; Dinaux, archæologist; and Savalle, inventor of the well-known apparatus for distillation which bears his name. The following are amongst the most notable names in the obituaries of other countries:—The Marquis Costa de Beauregard, of the Imperial Academy of Savoy, and the Turin Academy of Sciences; Dr. Gerling, Director of the Masbourg Observatory; the Greek savant, Bona; Professor Casper, of Berlin; Franklin Bache, the great grandson of Benjamin Franklin; Peretti, the Roman chemist; Rudolph Wagner; Barnontz de Jassy; Hohenegger, the geographer of the Carpathian mountains; the learned Dane, Charles Rafn; Struve, the Russian astronomer; the traveller Junhug; the Hebrew linguist, Rabin Sachs, of Berlin. Amongst painters, Germany lost R. S. Zimmermann, of Bavaria; Belgium, Gustave Pierron, Henri Julien de Stoop, of the Academy of Brussels, and Charles Robert, killed while hunting; and Switzerland, the celebrated landscape painter Calame, the illustrator of the Upper Alps, famous also for his etchings and lithographs. Belgium has also lost the architect Roeland, Professor at the University and Schools of Art, who built the Palais de Justice, the University, the theatre and casino of Ghent, and an immense number of hospitals, churches, and other public buildings, in various Belgian towns. Rome lost, amongst other artists, Raffaello Castellini, Director of the Mosic School attached to the Vatican, and who executed the wonderful works, the "Sybille de Cumæ," after Domenichino, and "Saint Jean Baptist," after Guercino, which appeared at the Great Exhibition of 1851, and now are at the Tuileries.

Publications Issued.

A TREATISE ON ORDONANCES AND ARMOUR. By Alexander L. Holley, B.P. (E. and F. N. Spon.) This includes descriptions, discussions, and professional opinions concern-

ing the material, fabrication, requirements, capabilities, and endurance of European and American guns for naval, sea-coast, and iron-clad warfare, and their rifling, projectiles, and breech-loading; also results of experiments against armour, from official records, with an appendix referring to gun cotton, hooped guns, etc., etc. There are 493 illustrations.

JOURNAL OF THE PROCEEDINGS OF THE LINNEAN SOCIETY. Vol. viii., No. 30. (*Longmans.*) Contains the following papers:—The Oesophagus of the Ruminantia, by Wm. Rutherford, M.D. Description of New Species of Hymenopterous Insects, from the Islands of Sumatra, Sola, Gilolo, Salwatty, and New Guinea, collected by Mr. A. R. Wallace; by Mr. Frederick Smith. Account of a Heronry and Breeding-place of other Water Birds in Southern India; by John Shorter, M.D., F.L.S. Brief account of the Myrmica Kirbil, as found in Southern India, by John Shorter, M.D., F.L.S. Description of New Species of the Dipterous Insects of New Guinea; by Francis Walker, F.L.S.

THE LONDON, EDINBURGH, AND DUBLIN PHILOSOPHICAL MAGAZINE. Fourth Series. Vol. 29, No. 193. (*Taylor and Francis.*)—The January number contains articles as follow:—"Researches on the Mineralogy of South America," by David Forbes, F.R.S.; on "The Relative Heating, by Solar Radiation, of the Soil and of the Air, on a Mountain and in a Plain," by M. Charles Martens; on "A Case of Stereoscopic Illusion," by C. J. Monro; note on "A Quartic Surface," by A. Cayley, F.R.S.; on "The Approximate Graphic Measurement of Elliptic and Trochoidal Area, and the Construction of a Circular Arc nearly equal to a given Straight Line," by W. J. Macquorn Rankine, F.R.S.; on "Calcescence," by Dr. C. K. Aikin; on "The History of Negative Fluorescence," by John Tyndall, F.R.S.; note on "The History of Energy," by P. G. Tait, M.A.; on "Thermal Radiation," by Professor Magnus; on "The Work or Potential of Torsion: New Method of Establishing the Equations which regulate the Torsion of Elastic Prisms," by M. de Saint Venant; the proceedings of learned societies, and intelligence and miscellaneous articles.

Notes.

THE MEMORIAL TO H.R.H. THE PRINCE CONSORT.—The massive blocks of granite intended for the base and pedestal of the Memorial to His Royal Highness the Prince Consort, have arrived at Limehouse. The blocks are about to be polished at the works of Mr. Kelk, the contractor for the erection of the Memorial, and when that operation is completed they will as speedily as possible be placed in position. So massive and weighty are these blocks in their undressed form that their removal from Limehouse to Hyde-park was an object of considerable mechanical interest. The stone is said to be of singular beauty, compactness, and durability. It is taken from the quarries of the Scottish Granite Company, in the Isle of Mull. It is of a beautiful pink red colour, capable of a polish equal, if not superior, to the finest marble, while it possesses in abundance all the properties necessary to enable it to resist the chemical action of the atmosphere. In a climate like ours, and for such an object as this National Memorial, the property of resisting the action of the atmosphere is one of supreme importance. Several of the lighthouses on the West coast of Scotland, which have stood the test of innumerable storms and the action of the severest frosts, are constructed of this granite. It has also been used in the construction of various harbours of refuge, in the building of the Liverpool Docks, the harbour works at Greenock, in the foundations of Westminster Bridge, and for the foundations of the Thames Embankment. The monolith or obelisk originally proposed for the Memorial was to have been taken from these very same quarries. The

same stone has been selected for the immense red granite columns forming part of the designs of the new bridge at Blackfriars.

CELTIC RELICS.—The Museum of Vienna has just received from M. Karl Zugmayer, of Waldeck, in Austria, an interesting collection of utensils and ornaments, in metal, found in the hollow of a rock, beneath a layer of granite. There seems little doubt that the objects in question are of Celtic origin. Amongst the most remarkable articles are two golden discs, a number of double spirals, arranged in the form of opera glasses, very carefully made, but of which the application is not even guessed at, some bracelets, and two heavy copper hatchets. The discs are respectively about five and six inches in diameter, and weigh together thirty-five golden ducats. They are ornamented with several rows of precious stones. They are believed to be the insignia of chiefs or priests, who wore them on their breasts. Some few years since a number of other precious objects, belonging to the earliest time of the Christian era, were found at Muthmanskorf, a village near which this new discovery was made.

ELECTRIC BELLS AND FIRE INDICATORS.—Some time since an ingenious electric tell-tale, invented by Mrs Sax, was noticed in the Society's *Journal*. He has now perfected an arrangement by which a bell is rung by the electric current, and at the same time a disk is brought to view, showing from which room the signal is sent. It consists essentially of an electric bell, which is placed in a situation where it may be seen by the persons whose attention it is wished to call. Near this is suspended the indicator shown at Figure 1. In the room or rooms from which the messages are to be forwarded, several buttons, represented at Figure 2, are placed against the wall: these correspond in number with the indicator; on pressing one of these buttons with the finger, the bell, however distant, is rung loudly, and a central red disk, as shown at numbers 1, 3, and 5, of the indicator, makes its

FIG. 1.

appearance. It is obvious that if the press buttons are situated in different rooms, the attendants, seeing the numbers marked on the indicator, are at once made aware of the room from whence the signal proceeds. If desired, the whole of the press buttons may be placed in one room, and made to signal different messages; thus, instead of the red disk, the name of the person or article required may be shown at the aperture of the indicator. For example, from the bar of an hotel, the waiter, ostler, boots, or chamber-maid, etc., could be called as required. The bell continues ringing so long as the button is kept down.

FIG. 2.

to the multifarious uses to which this indicator, constructed, could be applied, it may readily be adapted as a fire indicator, and this is effected by action of the press button shown at Figure 2; as a metallic thermometer, which can be set to measure desired; and when that degree of heat is reached, it makes the contact, completes the electric circuit, and causes the bell to ring violently so long as the temperature remains. It thus becomes a fire warning signal of danger from any room or place where it may be placed, to the sleeping apartment manager or superintendent. The fire button is made to act on a reduction of temperature given degree, and if then placed in a hot-house, it attracts the attention of the gardener to the sudden onset of a frost, which, if unnoticed, might destroy of many months' care and attention.

WORKS' CLUB.—The subjects to be brought for discussion during the present year include—"Lessons in Education," to be proposed by Mr. E. of Rugby; "The Breeding and Management of Cattle," by Mr. S. G. Stearn, of Brandeston, Wickham; "The Management of Grass Land," by Prosser; "The Importance of Shelter and Cover for Farm and the Homestead," by Mr. J. Bailey; "The Management of Benefit Societies in the Districts," by Mr. Charles Howard, of Bedford; "Breeding and Management of Cattle," by Mr. W. W. of Bayaham Court, Herefordshire. A prize of not less than ten guineas, will be given by the Committee for the best paper read during the year.

Correspondence.

ART-WORKMANSHIP.—SIR,—An inspection of the exhibition of Art-Workmanship now exhibiting at the Crystal Palace, afforded me great gratification, as it is in those applications of the Fine Arts to the most available for domestic adoption, and the completeness of detail is evidenced to such an extent that we are in a very hopeful state of the branches of the Fine Arts represented at the exhibition. The wood carvings and the specimens of work especially attracted my attention, for it is in these two branches of art are of such a nature, although for the execution of grand works of art, resort to great masters and expensive materials, so much that is pleasing and profitable might be effected by the comparatively untutored man of the Working Men's Exhibitions, which are now going up around us, were to direct the attention of the working men to the production, from suitable materials, of wood carvings (not in expensive woods) and of work in cheap materials; moreover, the art of marquetry and inlaid work, as applied to furniture, would most likely be very successfully carried out by our artisans and their families. It is certainly much more desirable that a man should devote his leisure hours to the production of furniture and ornamental objects for the house, than that he should spend years in stitching together pieces of fabric to form a patchwork bed coverlet, or

to the production of things of the ordinary type and character, of an uncouth appearance and unartisan-like finish. In all these branches of art that I have recommended, if we eschew elaborate productions, much may be done with so simple a tool as a sharp penknife or cutting instrument. What is wanted is the publication of suitable designs, with some simple and pertinent directions for the worker; possibly the announcement of some prizes for the best specimens of amateur work would facilitate progress. Even if the works produced by the amateurs should be of little value (though if the effort be sustained they must eventually be of some value), yet the practical acquaintanceship with art which will result must be a public good. It will, at any rate, be adding a new source of pleasure to the people's enjoyments, and eventually be of advantage to our artists, as it will increase the circle of those who consider the acquisition of objects of art as almost things of necessity; and, in any case, amateur workers must find instructive amusement in their work.—I am, &c.,—T. W. CAMPBELL.

London, 11th January, 1865.

ART-WORKMANSHIP.—SIR,—I was unable to attend on the 2nd inst. to make a suggestion, and beg most respectfully to do so by letter, viz., that one of the prizes should be for apprentices only, with less work than the present piece of ornament, as the masters generally will not give them any time (Messrs. Hunt and Roskell being a most liberal exception) to compete, and it is taxing their leisure too much to take about three hundred hours from it in six months. This is one of the causes of there being so few; it would also induce many more to try, if they were all youth, the timid would try as well as the more confident. It has been suggested that the selection of subjects should be left to the workman. I think there is very great objection to this, the workman generally not being allowed to design, simply because he is not educated for it, consequently you would have a great deal of trash sent in. On the contrary, while they are selected by you, they are sure to be examples of the highest order, and the study necessary to work them properly will be sure to improve the best workmen's taste, and will ultimately do a deal of good in the working of metal, and, I trust, will answer the noble end you have of improving the Art-Workman.—I am, &c., F. HOLLIDAY.

14, Nailour-street, Islington, Jan. 29, 1865.

ART-WORKMANSHIP.—SIR,—This is to add a few observations to those I made at the meeting held at the Society's House on the 2nd instant. I do not think I made myself quite clear about the time allowed for the execution of the works; I think that, so far as my own business is concerned, the time allowed was ample, as it included the whole of the summer months; the past year was rather an exceptional one with us; advertisements for silver engravers were of weekly occurrence, and most had to work over-hours, so as to leave no time for the execution of so difficult a work. I have been in the habit of telling the young men whom I train to the business, that slack times are our golden opportunities for improvement—each one is then able to follow his own bent, and great advance is generally made in knowledge and skill. The chairman correctly observed that it is to the rising generation of art workmen that these competitions will be most beneficial; I will add that it is important that men of mature years should give their time up to the furtherance of so good a cause. In my own workshop every stage of the process of engraving my competitive specimen was watched with the keenest interest by the young men and apprentices I am training; and I cannot doubt that seeds have been thereby sown which in time will show their fruit in the Society's Hall. Experienced engravers, to whom I have shown the photograph selected for competition, have strongly objected to the labour necessitated by the chequered background. Doubtless it requires much time and care for its proper execution, but I have found in it a great source of effect—it acts as a middle tint, giving powerful relief to the strong lights and

shadows on the arabesque; and when we have mastered the difficult task of niello filling-in, it will prove a great means of giving due effect in graver-work. I think the Council would do well to apply a higher test of our power of drawing in the future competitions among engravers; I think it would tend to bring forward our most skilful men. In this year's work we had only to make a careful tracing; and I beg leave to make the following suggestion:—That we be invited to make a reduced copy of some figure-work of a high character; for instance, the South Kensington photograph of Marc Antonio's engraved figure of *Luciece*, the drawing of which on the copper is ascribed to *Raffaello* himself. The figure is seven inches in height; we might be invited to reduce it to four and a half or five inches; it would be a high test of our drawing capabilities. I would further suggest that, in order to give us an opportunity of showing whether we are capable of producing something with the stamp of originality about it, we be allowed to surround the figure with an arabesque border, say an inch in width, and comprising masks and emblems appropriate to so tragic a subject; a prize might be offered for the figure alone, and an additional prize to be competed for by those who felt sufficient confidence in themselves as to make an attempt at an original composition. In the matter of advertising, I believe the best means of making the offers of the Council known in the provincial towns, will be to advertise in the local newspapers of largest circulation. In this town the *Sheffield and Rotherham Daily Independent* and the *Sheffield Daily Telegraph* are largely circulated among the workshops. I would advise the insertion of the Council's programme for the year in these papers, three times a week for two weeks. I believe that all who are interested in this town would then know of it. There is every appearance of a brisk demand for art-work in the opening year; the Council must not, therefore, feel surprised if they meet a smaller number of responses to their offers than they desire and expect; but I have not a shadow of a doubt that these competitions will grow in importance year by year. Slack times follow busy as surely as winter follows summer, and when they again come round I believe you will find the walls covered with competitive examples; men will then in effect say, "I am here, capable of executing work like this, will any one employ me?"—I remain, &c., G. MCKENZIE.

12, Tudor-street, Sheffield, Jan. 7, 1865.

MEETINGS FOR THE ENSUING WEEK.

- MON.** ...Society of Arts, 8. Cantor Lectures. Mr. B. Waterhouse Hawkins, "On the Reproduction of Natural Forms by Art and Manufacture." Lecture IV. R. Geographical, 8. Capt. Sherard Osborn, R.N., C.B., "Exploration of the North Pole." Entomological, 7. Annual Meeting. British Architects, 8. Medical, 8. Dr. James Jones, "Inflammation as an Exciting Cause of Tuberculosis."
- TUES.** ...Medical and Chirurgical, 8. Civil Engineers, 8. Mr. T. Hawthorn, "Description of the Port and Docks of Marseilles." Zoological, 8. Ethnological, 8. 1. Mr. Wallace, "On Civilisation in North Celebes." 2. Prof. Busk, F.R.S., "On Human Remains from Gibraltar." Royal Inst., 3. Prof. Tyndall, F.R.S., "On Electricity."
- WED.** ...Society of Arts, 8. Mr. C. F. T. Young, "On the Best Means of Protecting London from the Ravages of Fire." Geological, 8. 1. Mr. Julius Haast, "On the Excavation of Valleys by Ice." 2. Mr. James Bryce, "On the Order of Succession in the Drift-beds of Arran." 3. Mr. E. Ray Lankester, "On the Sources of the Mammalian Fauna of the Red Crag." Communicated by Prof. Huxley. Archaeological Assoc., 8.
- THURS.** ...Royal, 8. Antiquaries, 8. Philosophical Club, 6. Royal Inst., 3. Prof. Tyndall, F.R.S., "On Electricity."
- FRI.** ...Royal Inst., 8. General Sir H. Rawlinson, K.C.B., "On the Results of Cuneiform Discovery to the present time."
- SAT.** ...R. Notanic, 3. Royal Inst., 3. Prof. Marshall, F.R.S., "On the Nervous System."

Patents.

From Commissioners of Patents Journal, January 13th.

GRANTS OF PROVISIONAL PROTECTION.

- Autograph stamps—3198—Hon. J. Hay.
Boots and shoes, manufacture of—3194—T. and J. Fagg.
Brushing the hair, mechanical apparatus for—3167—C. E. Bryant and S. Middleton.
Carpets, &c., manufacture of—7—J. Spencer and N. Broomhead.
Cavalry stables, connector applicable to bales used in—3211—J. P. Robinson.
Coke ovens—3214—H. Hicklin and C. Pardoe.
Coke ovens—3222—J. B. Breckon and R. Dixon.
Drying machine, centrifugal—3204—J. Rowberry.
Entertainment, construction of houses of—1—W. Muir.
Fan blowers—23—W. Ager.
Farinaceous food, article of—2684—B. R. Keith.
Fire-arms—3132—A. H. Renton.
Fire-arms, breech-loading—2912—J. Snider, jun.
Fire-arms, &c.—3186—R. A. Brooman.
Glass house pots, manufacture of—3075—E. Brooke, jun.
Governors—3169—M. Henry.
Governors—3182—J. Byrne.
Gun barrels, manufacture of—3111—F. A. Le Comte de Fontaine-neau.
Heavy bodies, apparatus for moving—3153—D. Millar.
Household fires, lighting—3180—J. G. Aram.
Hydrocarbon fluid lamps, burners for—3245—A. S. Macrae and A. Bayley.
Iron, furnaces used in the heating and melting of—3116—J. Ellis.
Jute, &c., treatment of—3191—J. Paterson.
Lamp feeders, construction of—3178—H. Edmonds.
Liquids, &c., warehousing or storing—3241—P. C. P. L. Prefontaine.
Looped fabrics, machinery for producing—3225—J. & W. Thornt.
Manual power, carriages propelled by—3259—T. Du Boulay.
Marine steam engines, anti-saline coating for—2605—L. Paviot.
Mine shafts, preventing accidents in—3206—C. H. Taylor.
Mules for spinning—21—J. Knowles and J. Banks.
Mules for spinning and doubling—3237—J. Dodd.
Nuts, manufacturing metallo—3186—G. Haseldine.
Ordnance, mounting—3077—A. Moncrieff.
Ordnance, preparing charges for, &c.—3231—D. Sutherland.
Oxygen gas, manufacture of—5—J. F. Parker and J. Tanner.
Paper board, machines for making—25—J. F. Jones.
Paper, manufacture of—15—L. D' Aubreville.
Pianos, manufacture of—3224—J. Bardies.
Pitch, treatment of—9—R. Irvine.
Portland cement, manufacture of—3221—J. Cleaver.

Announcements by the Council.

CANTOR LECTURES.

"ON THE REPRODUCTION OF NATURAL FORMS BY ART AND MANUFACTURE." By B. WATERHOUSE HAWKINS, Esq., F.G.S., F.L.S.

Mr. Hawkins will conclude his Course, on Monday Evening next, as follows:—

JAN. 30TH.—LECTURE V.—On Ceramic Manufactures, with the Influence of the material on the design and its successful production—modern Terra-Cotta, Della Robbia ware, Majolica, and Faïence.

These Lectures are open to Members free of charge, and a Member has the privilege of introducing ONE Friend to each Lecture. A set of tickets for this purpose has been sent to every member.

Professor Ansted's Course of Six Lectures, on "The Applications of Geology to the Arts and Manufactures," will commence on Monday Evening, the 6th February.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

FEB. 1.—"On London Sewage, from the Agricultural Point of View." By J. CHALMERS MORTON, Esq.

FEB. 8.—"On the Claims of Authors and Inventors to Property in and Protection for Designs and Inventions first published at Industrial Exhibitions." By THOMAS WEBSTER, Esq., F.R.S.

ART-WORKMANSHIP.

The following is a list of the Prizes awarded. The judges were Richard Redgrave, Esq., R.A., M. Digby Wyatt, Esq., and John Webb, Esq.:—

1ST DIVISION.

WORKS EXECUTED FROM PRESCRIBED DESIGNS.

CLASS 1.—CARVING IN MARBLE, STONE, OR WOOD.

(a.) *The Human Figure*.—Work executed in marble or stone, after the Boy and Dolphin cast from a chimney-piece, ascribed to *Donatello*.—Four works sent in.—1st prize of £15 to G. T. Sherborn, 59, Ponsoby-place, Millbank, S.W.; 2nd prize of £7 10s. to Alexander Kenmure, 48, Pancras-square, N.W.

(b.) *Ornament*.—Work executed in marble, stone, or wood after a carved chair-back in the South Kensington Museum.—One work sent in.—1st prize not awarded; 2nd prize of £5 to James Stuart, 7, Pancras-square, N.W.

(c.) *Ornament*.—Work executed in stone, after a *Gothic bracket* in the Architectural Museum.—Three works sent in.—1st prize of £10 to T. V. Wran, 65, Lambeth-walk, S.; 2nd prize of £5 to John Barker, 7, Draycot-street, Sloane-square, S.W.

(d.)—Work carved in wood after a design by *Holbein*.—One work sent in.—1st prize not awarded; 2nd prize of £10 to W. H. Baylis, 69, Judd-street, W.C.

(e.)—Work carved in wood after the *Head of a Harp* of the period of Louis XVI.—One work sent in.—1st prize not awarded; 2nd prize of £7 10s. to T. E. Mayle, 17, James-street, Camberwell-new-road, S.

(f.) *Ornament*.—Work carved in wood after an *Italian picture frame*.—No works sent in.

CLASS 2.—REPOUSÉE WORK IN ANY METAL.

(a.) *The Human Figure as a bas-relief*; after *Raphael's "Three Graces"*.—Four works sent in.—1st prize not awarded; 2nd prize of £5 to W. Holliday, 14, Nailour-street, Islington, N.

(b.) *Ornament*.—Work executed after a Flemish salver in the South Kensington Museum.—Three works sent in.—1st prize of £5 to Septimus Beresford, 29, Myddelton-street, E.C.; 2nd prize of £3 to H. R. Batchelor, 149, St. John's-street-road, E.C.

CLASS 3.—HAMMERED WORK, IN IRON, BRASS, OR COPPER.

Ornament.—Work executed after a portion of the Pediment of a Gate (German work, date about 1700), in the South Kensington Museum.—Three works sent in.—1st prize of £7 10s. to T. Winstanley, 10, Arthur-street, New Oxford-street, W.; 2nd prize of £5 to J. Zobel, 189, Euston-road, N.W.; extra prize of £3 to W. Letheren, Llanedown Iron Works, Cheltenham.

CLASS 4.—CARVING IN IVORY.

(a.) *Human Figure in the round*.—After an Ivory, by *Fleming*.—Two works sent in.—No first prize awarded.—Two second prizes of £10 each awarded; one to J. W. Bentley, 22, Sherwood-street, Golden-square, W.; and one to John Richards.

(b.) *Ornament*.—Work executed after a pair of *Tablès*.—No works sent in.

CLASS 5.—CHASING IN BRONZE.

(a.) *The Human Figure*.—Executed after a reduced copy of "*Clytie*."—One work sent in.—1st prize of £10 to T. Nichols, 4, Everilda-street, Hemingford-road, N.

(b.) *Ornament*.—Work executed after *Goutier*, from a cabinet in the possession of Her Majesty the Queen.—Nine works sent in.—1st prize of £10 to R. E. Barrett, 26, Harrison-street, Gray's-inn-road, W.C.; 2nd prize of £7 10s. to H. J. Hatfield, 16, Alfred-street, Tottenham Court-road, W.C.

CLASS 6.—ETCHING AND ENGRAVING ON METAL—NIELLO WORK.

Ornament.—Work executed after arabesques by Lucas Van Leyden, 1528.—Two works sent in.—1st prize of £10 to Gilles Mackenzie, 12, Tador-street, Sheffield. 2nd prize not awarded.

CLASS 7.—ENAMEL PAINTING ON COPPER OR GOLD.

(a.) *The Human Figure*.—After *Raphael's* design of the *Three Graces*, executed in *grisaille*.—No works sent in.

(b.) *Ornament*.—Executed after a German arabesque (16th century).—No works sent in.

CLASS 8.—PAINTING ON PORCELAIN.

(a.) *The Human Figure*.—After *Raphael's* "*Two Children*," in the cartoon of "*Lysistrata*."—Seven works sent in.—No prizes awarded.

(b.) *Ornament*.—Executed after arabesques by Lucas Van Leyden, 1528.—Two works sent in.—1st prize of £5 to J. B. Evans, South-street, Mount Pleasant, Fenton, Staffordshire Potteries.—No second prize awarded.

CLASS 9.—DECORATIVE PAINTING.

(a.) After an ornament, from *Castel R. Pandino*, near Lodi, from a drawing in the South Kensington Museum.—Two works sent in.—1st prize not awarded.—2nd prize of £3 to John Hank, George-street, Stoke-upon-Trent.

(b.) *Ornament*.—Executed after a picture frame, in the South Kensington Museum.—No works sent in.

CLASS 10.—INLAIS IN WOOD (MARQUETRY, OR BURL), IVORY OR METAL.

Ornament.—Executed after a specimen in the possession of the Hon. John Ashley.—One work sent in (metal).—1st prize of £5 to E. A. Millward, 35, Little Clarendon-street, Brompton-town, N.W.

CLASS 11.—CAMÉO CUTTING.

(a.) *Human Head*.—After *Wyon's* heads of the Queen and the Prince Consort, on the Jurors' medal of 1851.—Two works sent in.—1st prize not awarded.—2nd prize of £5 to James Ronca, 156, King's-road, Chelsea, S.W.

(b.) *Animal*.—Work executed after *Wyon's* "*St. George and the Dragon*," on the Prince Consort's medal.—One work sent in.—No prize awarded.

CLASS 12.—ENGRAVING ON GLASS.

Ornament.—Work executed after arabesques by Lucas Van Leyden, 1528.—No works sent in.

CLASS 13.—WALL MOSAICS.

Human Head.—After *Bertini*, of Milan.

General competition.—Three works sent in.—1st prize

of £15 to Samuel Cooper, Longfield-place, Hartsill, Stoke-upon-Trent. 2nd prize of £10 to G. H. Stevens, Lambeth Glass Works, Carlisle-street, S.

Female competition.—One work sent in.—1st prize not awarded. 2nd prize of £10, to Miss E. Massey, Windmill-lane, Brantford, W.

CLASS 14.—GEM ENGRAVING.

(a.) *Human head*.—After an original in the possession of John Webb, Esq.—Three works sent in.—No prizes awarded.

(b.) *Full-length figure*.—After an original in the possession of John Webb, Esq.—One work sent in.—1st prize not awarded; 2nd prize of £5 to John Wilson, 14, Leicester-place, W.C.

CLASS 15.—DIE SINKING.

Human head.—After the head of the Prince Consort, by *Wyon*, on the Society's medal.—Five works sent in.—1st prize not awarded; 2nd prize of £5 to John Hatchett, 5, Gloucester-terrace, Kennington-park, S.

CLASS 16.—GLASS BLOWING.

Ornament.—After an original in the South Kensington Museum.—No works sent in.

CLASS 17.—BOOKBINDING AND LEATHER WORK.

(a.) *Bookbinding*.—After an Italian specimen in the South Kensington Museum.—One work sent in.—1st prize of £7 10s. to Louis Genth, 15, Broad-court, Bow-street, W.C.

(b.) *Leatherwork*.—Outside covering of a jewel casket. Original in the South Kensington Museum.—No works sent in.

CLASS 18.—EMBROIDERY.

Ornament.—After a German example in the Green Vaults at Dresden, or an Italian Silk in the South Kensington Museum, No. 7468.—No works sent in.

2ND DIVISION.

WORKS EXECUTED WITHOUT PRESCRIBED DESIGNS.

WOOD CARVING.

(a.) *Human figure in alto or bas-relief; animals or natural foliage may be used as accessories*.—Twelve works sent in.—No first prize awarded.—2nd prize of £15 to Mark Rogers, 111, Tachbrook-street, S.W., for a carving, "*Spring*," a Child's Head. 3rd prize of £10 to James Griffiths, 8, Addington-place, York-road, S., for a carving, "*Cain preparing his Sacrifice*." Extra prize of £3 to T. W. Wallis, Louth, for a carving of a Child's Head, "*Hope for the Future*."

(b.) *Animal or still life. Fruit, flowers, or natural foliage may be used as accessories*.—Five works sent in.—2nd prize of £7 10s. to T. W. Wallis, Louth, for a carving of "*Wagtail and Fly*." 1st and 3rd prizes not awarded.

(c.) *Natural foliage, fruit, or flowers, or conventional ornament in which grotesque figures or animals may form accessories, preference being given where the work is of an applied character for ordinary decorative purposes, as representing commercial value*.—Nine works sent in.—No first or second prizes awarded.—Two third prizes of £5 each awarded; one to George Murray, 6, Claremont-place, Henderson-row, Edinburgh, for a carving of a Frieze; and one to W. M. Holmes, 101, Dean-street, Soho, W., for a Tripod-stand. Extra prize of £3 to George Lock, 26, Albert-street, Camden-town, N.W., for a carving of Festoons of Flowers.

An extra prize of £5 to Gerrard Robinson, 14, Duke-street, Manchester-square, W., for carvings of the human figure in the round.

Proceedings of the Society.

CANTOR LECTURES.

FOURTH LECTURE.—MONDAY, JAN. 23.

The argument which Mr. HAWKINS had endeavoured to sustain, on the three previous occasions on which he had addressed the Society, on the subject of the Reproduction of Natural Forms by Art and Manufacture, had been to show that the education of the hand, with regard to art, continues to be in excess of that of the mind. To attain to any degree of fame in the higher branches of art, the artist must possess some innate feeling, but as there were those who could write and speak good English without being historians or poets, so there were artists possessing a certain amount of good sense, which, when it had acquired good taste by education, could be of more real service to manufacturers than the highest ideal powers when not submitted to a well-regulated mind. But the artist who was intending to aid manufacturers must obtain some knowledge of the process and materials by which his works were to be multiplied. On the present occasion it was Mr. Hawkins's intention to call their attention to metal work. The various metals—iron, brass, copper, and the precious metals—were so constantly used in the everyday necessities of life, from the cottage to the palace, and in our churches and other public buildings, that there was a vast demand for the combination of art with these materials. Mr. Hawkins sketched on his black canvass several instances of defective designs in metal work, pointing out the paucity of invention, which induced our artists to become mere imitators. He censured the incessant use of reproductions of flowers in every material—wood, leather, gutta-percha, porcelain, and iron. He also showed how unfit feathers, flowers, and ribbons were to form part of the decorations of cast-iron gates; and even when water-lilies were introduced very appropriately into a design for a drinking-fountain, he remarked that had the artist exercised his thinking faculties he would not have placed these flowers at the top of a high arch formed by tree branches, in total violation of their natural position, which was floating horizontally on the surface of the water. Mr. Hawkins proved the necessity for a knowledge of the process of casting to those who design models for reproduction in metal, by demonstrating the difficulties which were often thrown in the way of the moulder by the inattention of the artist to the requirements of the process. If the designer had merely learnt to draw, and not to model, he would find great difficulty in adapting his designs so as to avoid "undercuts," which render it necessary to divide the mould, thus increasing the labour and adding to the expense without necessarily enhancing the beauty of the work. During Mr. Hawkins's lecture his observations on metal casting were illustrated by a workman, who was making a sand-mould from a group of aureoas, which Mr. Hawkins had modelled some years ago. This process the lecturer rendered intelligible by his outlines on the black canvass. On the next occasion (Monday, Jan. 30) metal will be poured into the mould, to complete the demonstration of the process of metal casting so useful to the designer.

EIGHTH ORDINARY MEETING.

Wednesday, January 25th, 1865; WILLIAM HAWES, Esq., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Bonnerjee, W. C., 108, Denbigh-st., St. George's-rd., S.W.
Hill, Frederic, The General Post Office, E.C.
Peckett, George, 10, Aberdeen park, Highbury, N.
Perkins, Houghton, 25, Mortimer-street, W.

Robinson, Noel Hooke, 6, Great Queen-street, S.W.
Rodger, Captain William, R.N., 9, Shawfield-street, King's-road, S.W.
Sancton, Philip, 28, Cumberland-ter., Regent's-pk., N.W.
Smith, Colonel John Thomas, R.E., 27, Cannon-st., E.C.
Stone, George Graham, 78, Holland-park, W.
Sudlow, John J. J., 8, Manchester-buildings, S.W.
Thompson, Thomas C., 42, Belsize-park, N.W., and Sherburn Hall, Durham.
Tomline, William, 5, Whitehall-yard, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Haines, Alfred, Kensal-house, Harrow-road, W.
Knowles, S., Tottington, near Bury, Lancashire.
Mayson, J. S., Charlotte-street, Manchester.
Tremlett, Rev. Francis W., LL.D., The Parsonage Belsize-park, N.W.
Whitehead, J. B., Rawtenstall, Lancashire.

The Paper read was—

ON THE BEST ORGANIZATION FOR PROTECTING LONDON FROM THE RAVAGES OF FIRE.

By CHAS. F. T. YOUNG, Esq., C.E.

Fire, like the rest of the elements, when properly used and controlled, is an excellent servant and assistant to man; but, when it obtains the mastery, it is, as we find from past and continued experience, a most terrible and ruthless tyrant, destructive alike to life and property, and perfectly indiscriminate in its ravages. The palace and the hovel, the prince and the peasant, the old and the young, are equally open to its destructive influence; and it becomes the bounden duty of all to do their best to prevent its doing mischief, and confine its powers within those bounds in which it is found to act most beneficially for man.

Carelessness and wilfulness are the two best allies by whose influence it so frequently exceeds its bounds, and against these it is impossible always to guard; consequently we find, from the earliest ages, provision made for restitution or punishment, according to the origin of the fire, and in the case of wilfulness it was punished by death.

From a death by fire or burning we all instinctively shrink, and with reason, for a more fearful or terrific termination to one's existence cannot well be imagined; therefore, as when a fire once breaks out it is impossible to foretell the extent of its ravages, or the loss of life that may ensue, it is proper that the punishment of arson should be made most severe, and also that for culpable carelessness, the effect being the same though the motives may differ.

A large fire, especially amongst much inflammable material, is an awful and magnificent sight, and one usually as ruinous and fatal in its results as it is extensive and magnificent in appearance. In a few hours the labours of a lifetime, or even of a generation, disappear, leaving in their place a shapeless, useless mass of ruin, and the owners or dependents houseless or penniless, and frequently to commence again those labours and exertions that possibly another year or so would have rendered unnecessary.

To provide some means for counteracting these dreadful effects seems to have been a part of the business of every civilized nation from the earliest times; and there can be no reason to doubt that such means existed and were in use, in most of the celebrated cities of antiquity, such as Nineveh, Babylon, Tyre, and others; for it is difficult to believe that the engineers and mechanicians of those cities, whose talents and skill are so well known, would have omitted to provide some means of counteracting or extinguishing fires, the fearful ravages of which were well known and would be of such injury to their magnificent cities. That this was the case is rendered the more probable from our finding that Pliny the Younger

wrote to the Emperor Trajan asking permission to establish a fire brigade of 150 men, into which he proposed to admit only those of that business: and we find him stating that the town of Nicomedia was burnt, because of the laziness or indifference of the inhabitants, and from want of proper machines or apparatus for extinguishing the flames. When ancient Rome was rebuilt, every citizen was required to keep in his house "a machine for extinguishing fire;" but what these machines were we are not informed. As in those days there were buckets, mops, hooks and syringes, it is reasonable to suppose that they were the latter; for we find that the dimensions of these squirts, when employed for extinguishing fire, were generally regulated by those of the building in which they were to be used. Pliny, in speaking of fire machines, uses the term "Siphon," which by some is taken for pipes or water tubes; but in a passage from a fragment of a work of Apollodorus, the architect to the Emperor Trajan, we are told when a fire occurs in the upper part of a house and the "Siphon" is not at hand, to take leather bags and fill them with water, connecting long pipes to them; and then, by compressing the bags, the water will be thrown to certain heights; therefore it is fair to say, from this description, that whatever the "Siphon" may have been, it was evidently a fire engine; for if such a rude contrivance as that described was applicable in its stead, it must be tolerably evident that the "Siphon" was an efficient machine for the purpose.

The ancient Romans, we are told by Suetonius, maintained bands of trained fire-men called *fructuarii*, whose duty it was to extinguish fire; and these were also fire-men in all the provincial towns. Petronius mentions their cutting away with axes, and throwing water from buckets at fires. To the ancients who lived nearly 2000 years ago we are indebted for the modern manual engine, which was invented by Ctesibius, of Alexandria, an engineer of that city, who lived in the 165th Olympiad, or about 190 years B.C. His pupil, Hero, of the same city, describes one in his "Spiritalia," which had metal cylinders—metallic pistons—spindle valves, with guards to prevent their opening too far—a goose neck, formed by a kind of swivel joint—something like a union or coupling screw—the application of an air vessel—two pumps forcing the water through one pipe—and one lever to work both pumps; all these are features, some or all of which have been revived and brought forward in modern times as great improvements or inventions.

It would be tedious, would take up too much time, and be foreign to my present purpose, to give a consecutive account of the different laws, ordinances, rules and regulations, made from these times for extinguishing or controlling fires, but they will be found fully treated of in a new work on the subject shortly to be published: therefore I propose to commence with what has been done to protect London since the Great Fire of 1666. The enormous destruction of property by this tremendous conflagration seems to have convinced the Government and City authorities of the imperative necessity of some well regulated means and appliances for the controlling of fires, and Acts of Parliament and Common Council were passed to obtain them. The city was divided into four districts; each of the twelve companies and aldermen were to provide themselves with brazen syringes, leather buckets, ladders, pickaxes, shovels, &c.; and, to obtain the water required for the engines and squirts, pumps were ordered to be placed in all wells, and fire plugs in the several main pipes belonging to the New River and Thames Water Works.

In the official report or account of the Great Fire, dated Whitehall, September 8th, 1666, it is remarked that "this lamentable fire in a short time became too big to be managed by any engines," thus showing that some other apparatus besides the hand-squirts must have been in use. These hand-squirts were worked by three men, one on each side to hold and direct, and one at the piston-rod to force the water out, just the same sort of thing as was used some 1800 years before!

In 1708, the 6th year of Queen Anne, it was enacted that "each parish shall keep a large engine and a hand engine, and a leather pipe and socket of the same size as the plug or fire-cock (of the water mains), that the socket may be put into the pipe to convey the water clear to the engine," under a penalty of ten pounds. It also provided that the first person who arrived with a parish engine to extinguish a fire was entitled to 80s. reward; the second, 20s.; and the third, 10s.; provided the engines were in good order, "with a socket or hose or leather pipe." This Act, with the usual characteristic of English Acts of Parliament, contained no provision or regulation for the payment of the expenses of working these engines at fires, nor did it impose any obligation on each parish to take the engines to a fire; therefore, if the engines and required appliances were provided by each parish, the Act would be duly complied with, and they need not be used at all, but kept locked up, if it pleased the parish authorities to do so, without in any way contravening the provisions of it—a fine example of the legislative wisdom of the Solons of the 18th century.

In 1799, the owners and keepers of "other large engines" (not parish engines) were entitled to the same reward upon arriving with them and assisting in extinguishing a fire. In the same year, an Act was passed by which it was enacted, "That every servant by whose negligence or carelessness a fire should be occasioned, should forfeit one hundred pounds, or, in default, be imprisoned and kept to hard labour during eighteen months." In the case of setting fire to a house wilfully, it was made a capital offence, punishable by death.

From this time a period of nearly one hundred years elapsed, viz., to 1808, without any really efficient system for protecting the metropolis from fire being brought forward, or anything being done, except a little "tinkering" by Acts of Parliament, in relation to parish engines, &c. In 1808, however, Sir Frederick Morton Eden, the then chairman of the Globe insurance office, attempted to form a fire-engine establishment, for the protection of life and property from loss by fire. He proposed that each office should furnish 20 firemen; that all matters relating to appointments of firemen, and the business connected with the proposed establishment, should be managed by an Engine Committee; and that each office should pay an equal contribution towards the expenses of the establishment. By the end of the year, Sir Frederick was convinced of the time not being yet come, by finding that only one office, out of all the number, namely, the Atlas, could be got to join him; consequently he gave up the attempt.

About the year 1825, a union similar to that proposed by Sir F. M. Eden 17 years before, was formed by the Sun, Union, and Royal Exchange, who placed all their engines and men under one superintendent; and some time afterwards they were joined by the Atlas and Phoenix. On the 1st January, 1833, the London Fire Engine Establishment was formed, by ten of the insurance companies uniting, with the view of reducing the separate expenses of each office, and giving mutual assistance at fires. These ten offices were the Alliance, Atlas, Globe, Imperial, London Assurance, Protector, Royal Exchange, Sun, Union, and Westminster, and thus, after the lapse of a quarter of a century, was the system proposed by Sir F. M. Eden carried into practice, chiefly through the exertions of Mr. Bell Forde, a leading director of the Sun Fire Office, and the Brigade consisted of 89 men and 19 stations. Up to this period the engines and plant of individual offices, and those belonging to parishes, and some of the large private firms, were the only means available for use in case of fire; and at the present moment there exists no public means for this purpose, we being as it seems content to rely on private enterprise for that protection which it is the bounden duty of the public, and the public only, to supply; it being a matter of vital importance to the public, individually and collectively, that such means be provided and maintained in the highest state of efficiency.

tection obtained from the existence of parish of the most ineffectual character, though there are notable exceptions, such as St. Ann's, Soho, Islington, and a few others, for we find, from a report given by Sir Richard Mayne before the committee of the House of Commons in 1862 on the Metropolis, that they are "mostly at churches and houses, under the charge of beadle or private who are paid a trifling sum by the parochial authority. At great fires they are quite inefficient, and at small fires they are not wanted. There are 98 parishes in London which are bound by the old law to keep a beadle in each parish; if they do it, it is no doubt in an ineffectual manner." We also learn from the same source, that of the engines for which engine men and small rents are paid, one is said to be bricked up in a blacksmith's shop, and if a fire happened and services were required, part of the wall of the engine house would have to be pulled down to get the engine out. The man is paid for looking at it occasionally; with the view of seeing it does not run away of its own accord.

As a parish engine may be seen running express at the rate of about a mile and a-half an hour, it is pushed by half a dozen poor old worn out men from the workhouse, escorted by a crowd of idle ragamuffins of the neighbourhood, and in the state of perfect order and efficiency, that when a fire occurs it cannot be put to work; this has happened under my own notice.

I give the following capital description of the mode of operation, and arrival at, a fire, of a parish engine:— "I never saw a parish engine at a regular fire but once. It came up in gallant style—three miles and a-half an hour; there was a plentiful supply of water, and it was upon the spot. Bang went the pumps; the beadle cried; the beadle perspired profusely; but it was not until it was discovered, just as they were going to be put out, that nobody understood the process by which the engine was filled with water; and that eighteen minutes had been exhausted themselves in pumping for minutes without producing the slightest effect." I find, Mr. Wm. Baddeley, whose thorough and intimate acquaintance with London fires is so well known, on this subject in 1838, remarked, that "scarcely a fire occurs in the metropolis without the rehearsal of this absurdity; and it has been my lot to witness instances of this description, even more abominably than that which has been so graphically described by Boz." He also, in the same letter, stated of a great fire in which the Royal Exchange was burnt, though there were no less than 17 fire engines in the neighbourhood, one of the smallest engines only was put to work, and that, as a matter of course, would not work.

On several occasions, quite recently, we have had other instances of a most ludicrous character, two of which are sufficient to prove the disgraceful state of inefficiency of the present parochial system of means for fighting fires. A fire occurred last year in one of the most populous districts of the metropolis, to which an engine was brought out, the hose were laid out, the levers were worked, and worked up and down in a most enthusiastic manner, but all to no good purpose, for not a drop of water was thrown on the fire from the engine. A fire engine came past at the time, and, not understanding the reason of the fire being left perfectly unextinguished, stopped to see the cause, and found—it will be credited—that the suction hose had taken the water from the delivery, and the delivery that of the engine. It is needless to say that the fire destroyed the building in which it had broken out. In the next case a fire had been run to a fire some distance off, and arrived, and they began to see about getting to the fire, and found that they had come away without any water, consequently the engine could not be used. These instances looked upon as ludicrous in the extreme were

it not that they are far too serious and important facts for other than melancholy consideration, and convincing proofs of our utterly unprotected state at the present moment—a state which is a terrible disgrace alike to our authorities and ourselves—to our authorities for not having long since devised and carried out an efficient means for the purpose; and to ourselves for suffering such a state of things to exist, especially as we have the remedy in our own hands.

It is worthy of remark, that the tendency of the fires of the present time is to become of far greater extent than formerly, and to cause far heavier losses; whilst our means of controlling them are not increased in proportion. It is a fact that most of the large London fires, within a few years past, have occurred in what are termed (almost in ridicule it would seem) "fireproof" buildings, having either originated in or extended to them; and as in these so-called "fireproof" structures the most valuable goods and materials have been stored, on account of the assumed security afforded thereby, the losses have been correspondingly heavy. When once the fire has got hold of one of these buildings it is found to be a waste of power to attempt to save it; and the exertions of the firemen have been found to be better employed in preventing the fire from extending to the adjoining premises. This was particularly the case in the great fire in Gresham-street, which annihilated the "fire-proof" building in which it originated. These "fire-proof" buildings are invariably found, in case of catching fire, to "hold" the fire, and by this means render their destruction, and that of their contents, a dead certainty; and they are to all intents and purposes most efficient "blast furnaces," whenever they, or rather their contents, unfortunately become ignited. It may be noted that floor-cloth factories, the inflammable character of whose contents is well known, are required to be built of wood, it being considered far better for the entire building and contents originally ignited to be destroyed, than by making them "fireproof," and of a nature calculated to hold the fire, to run thereby the risk of burning a whole neighbourhood.

For some time past we have heard that the Government were to bring in a Bill to give them power to create and maintain a system for controlling and extinguishing fires in the metropolis, absorbing the men and plant of the present establishment of the insurance offices; but there seems no probability of this at present, nor is it on the whole desirable, seeing that they (the Government) have already quite as much, or more, on their hands than they can conveniently manage; nor is it probable that it could be done by them in that mode which is best calculated to make the required protection thoroughly complete, and of the nature required by the public. In the "Fires in the Metropolis Bill" it is proposed to begin with a tax of £65,000 per annum. The next proposition is that the protection of the metropolis from fire shall be entrusted to the Metropolitan Board of Works, who are to be empowered to purchase the existing plant of the London Fire Engine Establishment and levy such necessary rate on the ratepayers of the metropolis as may be required to meet the expenses of maintaining it; but this is a proposition I feel sure will be opposed by all the parishes of the metropolis, and the ratepayers generally, for though the insurance offices would have to contribute towards its maintenance, still it would be impossible to control the expenditure in a satisfactory manner, or to fix a point which should be the maximum the ratepayers would have to contribute. I think that this proposal also will not be the one calculated to protect the public in the manner required, and it will be agreed by most of us that we have quite enough rates already for other purposes, none of which, it may be remarked, decrease in amount, and that any further increase of them, either in amount or number, is far from desirable.

As an example of what these rates and taxes might amount to in maintaining a force of men sufficient to control the fires of the metropolis, it is estimated that it

would require a protective force of at least 500 men, in addition to the present staff (which would be only 1 in 6,000 of the population); and to keep up this staff as a paid brigade, would require us to be taxed for wages only to the extent of £37,000 per annum. This amount would of course be increased if more men were put on, and with London spreading out at its present rapid annual rate, it would not be very long before a larger sum would be required. Knowing, therefore, from present and past experience, how rapidly rates and taxes increase, it is but fair to assume that the extent and amount of a rate or a tax for the purpose of adequately protecting the metropolis from the ravages of fire, must be taken as an unknown quantity, but one nevertheless capable of unlimited extension; and for this very reason, if none other, we must one and all strenuously oppose it.

The Police Act does not and will not provide any appliances for extinguishing fire; and it is no part of a policeman's duty to make any attempt to do so, even when he sees it at the moment of the outbreak. The heavy police-rate (averaging 6d. in the £) will not admit of any men being spared for other duties than those of guardians of the peace; and even now we see frequent complaints in the public papers that their number is insufficient for this purpose. It is evident, then, that we cannot expect the required protection from the police, nor is it at all desirable that the fire-extinguishing arrangements of the metropolis should be left to them.

The time is evidently now arrived when the question of the most efficient, the cheapest, and easiest mode of thoroughly protecting the metropolis from the destructive ravages of fire, and providing a more effectual check to the tremendous conflagrations that have occurred so frequently of late, shall be set at rest; and the establishment of a truly Metropolitan Fire Brigade be accomplished; for, with the improvidence of an almost savage state of society, we have left ourselves at the mercy of the flames, and for more than a quarter of a century have shamefully neglected our duty in this respect, because the insurance companies arranged for extinguishing their own fires, by a set of men and plant; and to their inclination or otherwise we have trusted for help in extinguishing our own. It is neither just to the insurance companies, nor safe for ourselves, to trust wholly or even in part to their aid when fires occur. It should be remembered that their men and engines are designed and maintained by themselves simply for the protection of their own funds, and that there is no legal claim on them to maintain their establishment for the public benefit; but we have all grown into the false belief that we are entitled to look upon them as intended for the benefit of the public at large. No doubt, to a certain extent, they do confer this benefit; but all they can do with their present means and appliances, is far from sufficient for the daily increasing requirements; and we find that having to defray the cost of them, they stand, as is natural, on their undoubted right when they decline to augment it. What we now want is a complete and entire change of plan—one which does not inflict a compulsory maintenance of rates for the purpose, but brings into requisition that important and priceless principle—the VOLUNTEER SYSTEM—to whose energetic and chivalrous exertions we can trust with far greater certainty and satisfaction than to any paid system whatever.

It will, of course, be urged—as it was in the case of our volunteer riflemen—that they are not needed, that they cannot be made efficient, will not work as well as paid men, &c., &c.; and we have seen how all these sinister prognostications have failed. It may also be remembered that stronger reasons than these were urged against railways, and, in fact, against every improvement or “innovation,” as it is termed, but, in spite of all that could be urged to the contrary, they have invariably, when once started, gone ahead, and their most persevering and strenuous opponents are found amongst their staunchest supporters.

The Volunteer riflemen, it should be remembered, provide for a danger afar off and yet to come; but the volunteer firemen are ready and willing to deal with one that is in our midst, and may meet us at any corner at any moment, and who can at this moment say that he may not, even while I am speaking, require their services?

The old proverb says, “one volunteer is worth ten pressed men.” I prefer to place the word “paid” instead of “pressed.” The negation of self has contributed more than anything to the success of volunteering. The sacrifice of time and money which has been made by those who have entered the ranks of our citizen-soldiers, has given a solidity, an *éclat*, and a prominence to the institution, which cannot fail to make it a most efficient weapon of defence for the country.

So far as the spirit of volunteering to carry out any really honourable and useful purpose goes, I believe it exists in the highest degree in this country, possesses a steady permanency, and a brilliant ardour; and it is only necessary to point out the direction in which it is required, to ensure its enthusiastic and perfect development. By the proper carrying out, in an efficient manner, of the system of Volunteer Fire Brigades, we shall have the proud reflection that we have around our hearths, and amongst us and our families, a brave, fraternal band, who do not work for pay, and will therefore work more effectively, heartily, and enthusiastically; and, being actuated by the true volunteer spirit, being implicitly obedient to orders, well equipped, and thoroughly acquainted with their duties, will hardly fail to render most important service in the hour of danger. By forming efficient Volunteer Fire Brigades, it should be remembered that we are not only protecting our own lives and property, and thus rendering ourselves more secure from loss, but are also assisting to protect the little all of those poorer and less fortunate neighbours who cannot afford to insure, and to whom the loss of that little all, how small soever it may be, is nearly always total ruin. It must be borne in mind that everyone is deeply interested in the quick and efficient repression of fires, and in furthering to the best of his ability any practical and efficient means for the purpose; but it is surely unreasonable to suppose that such a means cannot be easily carried into effect, provided all will lend an earnest and willing hand to do so.

It is constantly said that paid firemen will work better than volunteers, because “every man will perform his duty more energetically when he is paid.” Now, I cannot, for a moment, admit that this is the case, and it will be very difficult to prove it. If paid men are best, how comes it that volunteers are always asked for when it is desired to do something very perilous or difficult—say spring a mine—storm a fort—lead a forlorn hope—rescue a shipwrecked crew—or some other hazardous undertaking? Surely, in such cases as these, where it is most important that everything should be well done, it must be admitted, from the above reasoning, that it is a mistake to allow the service to be performed by volunteers. The paid man, in all that he does, feels that he is giving an equivalent for that which he receives—and in practice will generally be found to give as much less as he can—but a very different feeling actuates the volunteer, for, as we have seen on hundreds of occasions, he throws such hateful considerations to the winds, and starts on his self-imposed task with a motive and an energy which a paid man can never know; and his unselfish exertions are certainly not less successful than those which some persons think require a pecuniary inducement to give them their assumed superiority.

Mr. Elihu Burritt, better known in this country as the “American blacksmith,” now the United States Consul at Birmingham, speaking of volunteer firemen, says, “it is one of the noblest objects aimed at that could nerve the manhood of brave men. The great battles they train themselves to fight, are midnight battles with the consuming fire; battles fought amid snow and ice in midwinter against the devouring element; charges home

in hand to pluck the burning homes of widows and orphans from destruction; battles in which there are ample scope and play for the best bravery of the human arm. These volunteer fire companies became so popular and numerous that there was one in almost every village in New England. In my own native town, with a population of about 6,000 souls, there were three of these trained bands, besides a juvenile company for even boys of twelve years of age, who would not wait, but formed a band by themselves for the drill and exercise. It is said that the Prince of Wales has manifested considerable interest in volunteer fire companies; perhaps what he saw in America will pre-dispose him to look favourably at their introduction into England. I have noticed that it is making a little stir in France; and I read the other day of the Emperor's reviewing a fire company at Vichy. One good company paraded in Hyde-park, well drilled, in attractive uniform, and with a highly-finished engine, and going through all the exercises and evolutions adopted on such occasions, I am sure would excite lively admiration, and I have no doubt that similar companies would be formed in all the large towns in the kingdom."

Now, if it be looked on as a meritorious action and an honour in the time of war, to assist at the peril of one's life in the destruction of life and property, because it is considered desirable to do so, it must at least be esteemed equally as honourable to risk one's life and limbs in the preservation of life and property in the time of peace. Let this once be granted, and we invest the position of a volunteer fireman with that honour and merit which are its just and proper due.

In Switzerland volunteer fire brigades exist, not only in cities and small towns, but also to a great extent in villages. The most respectable citizens vie with each other in eagerness and zeal to become members of such useful associations, which, however, consist of a fixed number of men. In some places the members are divided, a portion devoting themselves exclusively to the management of the fire engines, whilst others attend to the not less important task of taking immediate possession of the house on fire, saving what property they can and protecting the remainder. The order and method with which these volunteer fire brigades are conducted are deserving of the highest commendation, and their praiseworthy exertions are thoroughly appreciated by all who understand the motives of a volunteer fireman. In order that no delay may be experienced in taking out the engine to a fire, as sometimes happens from the temporary absence of the man in charge, two or three keys are distributed to an equal number of persons living near the engine-house, so that there may always be at least one key at hand when the engines are wanted.

"In several of the cities of Germany the whole of the householders of the district are members of a society for extinguishing fire, as well organised, as thoroughly drilled, and subject to as severe regulations as our militia or volunteers. The sound of the fire alarm bell calls each man to his post; the subdivision of labour is made; the nature and duties of that labour are known; system and science, as it may be termed, pervade the whole of their movements; seldom, if ever, does the fire extend beyond the place in which it originates, and very frequently it is extinguished without much mischief to the house in which it breaks out. It is a system and an association of this kind that we require in London."

The enormous advantages to be gained by the establishment of efficient Volunteer Fire Brigades throughout the United Kingdom, can hardly be sufficiently realised, the idea being a comparatively novel one; but of its superior economy there cannot be the least doubt. Let us take London for example, with an area of 700 square miles, on which the present fire engine establishment acts, which is assumed to be protected by 32 fire engines, nineteen stations, and one hundred and fifty men, costing the insurance companies some £27,000 per annum for its only partially efficient services, and let us supplement them

by a well drilled corps of volunteers, some 500 or more in number, and with some 60 stations, and the requisite plant, judiciously distributed over the area of the metropolis, thereby affording equal and instant protection alike to the insured and the uninsured, at a cost to the insurance offices of less than half of their present contributions. The advantages gained by such a change would not be long in making themselves apparent.

From the evidence given before the Select Committee, we learn that the insurance companies paid for extra labour only at the great fire in Tooley-street no less a sum than £1,100, and this to utter strangers, men who knew nothing about fires, or salvages; and it has been admitted in evidence before the committee above alluded to, that the gratuitous services of the volunteers were most valuable.

Taking the present annual expenditure of the London Fire Engine Establishment, and dividing it by the number of calls to fires received within the year, we get nearly £17 as the cost of each run. By the volunteer system all this expense might be avoided, and each district in London could be protected by its 500 volunteers without any cost at all, and as each suburb springs up the means of protecting it would be immediately found, and that too without interfering with the more populous and endangered districts.

In London something of the kind I have proposed is becoming an absolute necessity; for it will be found that at each of the large conflagrations which have occurred of late, nearly all the men and engines belonging to the Fire Engine Establishment have been congregated, thus leaving the remainder of London totally unprotected, and in a state of the greatest danger. When we reflect that the metropolis is daily enlarging in extent, its trade and population increasing, and the value of its goods and merchandise becoming hourly of greater amount, added to which is the great and increasing loss caused by each fire from these very facts, whilst the existing establishment is less able to cope with them, and cannot afford to increase its power from the constant and great expense incurred in its maintenance, which does not decrease, we can form an idea of the importance of this question.

The great fire at Tooley-street (which continued burning for a fortnight), and the great number of others, almost as destructive, which have so frequently occurred since, cannot fail to have shown to the public the total inadequacy of the means at present provided for the repression of fires in the metropolis. The *City Press*, in an article in a number for January, 1863, says:—"We want more engines, more men, more steam power, a general fund of some kind, to which all shall contribute in the ratio of their possessions, and one source of power for the administration of the whole."

The system of volunteer firemen, to supersede the abominably deficient plan of protection by parish engines, or, as is too often the case, no sort of protection at all, and also the expensive though not more efficient plan of paid brigades, is taking a strong hold on the minds of the public, who are beginning to see that by manning their own engines they obtain that efficient protection, that energetic will to combat the ravages of fire, which can only be obtained under a well-disciplined system of volunteers, a system which on all occasions proves its enormous superiority to any paid system.

The *Post Magazine and Insurance Monitor*, of the 10th December, 1864, in speaking of volunteer fire brigades, says that many of its readers "will be as much surprised as we are ourselves at the number of these valuable voluntary associations that have been formed for the protection of property and human life against the terrible casualty of fire."

I find that we have in Great Britain, at the present moment, no less than 43 Volunteer Fire Brigades, with all their engines and appliances. Of these there are, in London and the suburbs, 11 brigades, with a total of 194 members; 19 engines, one being a steamer; and the power in the number of men required to work the manual

engines represents 367 men; the total value of their plant and appliances being £8,670. The country brigades have 800 members; 70 engines, 1 steamer; representing a power of 1,200 men to work them; and the total value of their plant and appliances is estimated to be £14,000.

Of the country brigades, that of Alton was the first to employ a steam fire-engine, having obtained it at the close of last year; and the Lambeth Volunteer Brigade was the first to use it in London, having employed it nearly two years.

ABSTRACT OF VOLUNTEER FIRE BRIGADES.

COUNTRY.

Number of Brigades, 31.
Number of Members, 800.
Number of Engines—Manual, 70; Steam, 1.
Power of Engines, 1,200 men.
Value of Fire Plant, £14,000.

TOWN METROPOLIS.

Number of Brigades, 11.
Number of Members, 194.
Number of Engines—Manual, 18; Steam, 1.

Power of Engines, 367 men.
Value of Fire Plant, £6,670.

TOTALS.

Brigades, 42.
Members, 994.
Engines—88 manual; 2 steamers.
Power, 1,567 men.
Value, £22,670.

In contrast to London, with its population 3,000,000; an area of nearly 700 square miles to its paid fire establishment of 180 men; some 32 and 19 stations; and a property of the rateable over £900,000,000, let us place the city of Paris population of 1,696,166, where we find that the force of 1,270 men, 120 stations, and 180 outfits; all the men are soldiers, and, as is now country, everything is done on the military plan the volunteer system, it will be sufficient to take of New York—not including Brooklyn and Jersey both having their own fire companies—where for controlling fire consists of Volunteer Engine and Hook and Ladder Companies. The population of New York City is about 1,000,000, and we find have 55 engine companies and stations, 27 engines and appliances, 40 manual engines and 62 hose companies, with their appliances; and and ladder companies. The men in each company vary in number, some companies low as 18 and others as high as 50.—Total from The hose companies, of which there are 62, have to 25 men in each company.—Total hose in The hook and ladder companies, of which there have from 17 to 40 men in a company.—Total ladder men, 640, giving a grand total of men in controlling and extinguishing fire in New York alone, of 4,611 men. Attached to the engine are 52 hose tenders and 17 fuel tenders, all on the hose companies have 58 hose carriages and tenders; whilst the aggregate length of hose engines is no less than 15 miles 108 yards, or reach from the Royal Exchange to Darford. These particulars are derived from the report of John Decker, Esq., Chief Engineer to the Corporation of New York, and form an addendum to the state of things at present existing in London particulars of the Sapeurs-Pompiers of Paris obligingly forwarded, at my request, by M. de Dionne, "major-ingénieur" of that corps. Government establishment they do not publish for circulation, but the abstract of the corps, of the past year, have been copied out of the report.

Once introduced the system of Volunteer fire efficient and judicious management, carefully members only those physically qualified, and them properly with an efficient system; and then be the slightest reason to doubt their becoming a body as our volunteer rifles, whilst, if actuated by a very different spirit to that which amongst paid brigades, they will do their work in a smarter and more efficient manner, with far less by water, and an increasing desire to do better occasion when their services may be called into requisition. It cannot fail to prove most advantageous for the insurance offices, and the public, to support the volunteer system, which in Switzerland, America, Australia, and elsewhere is considered far superior to any paid system, and it give most excellent results, for by it any number of men can be obtained at a cost not depending on number but simply on the rent of the number established, and the expense of maintaining the and plant at these stations.

We have seen that Government admits the more extended and efficient means for controlling the metropolis (of which a most convincing afforded by the celebrated conflagration at Tool by their proposal for a Bill for this purpose,

seems just as far from becoming a fact, as when first talked about.

By establishing volunteer fire brigades in London, and also in all towns in the United Kingdom, with proper plant and appliances, and zealously contributing, according to our means and time, towards their establishment and maintenance, we remove the great difficulty out of the way of the government, namely, that existing between the government and the fire insurance companies, contributing to the London fire engine establishments, as was stated by Sir George Grey at the close of the late session, and given by him as a reason why the government bill was not brought forward. It seems to me that the Government might give a sum of money to be applied to the purchase of steam fire engines and appliances, and a certain annual grant for their maintenance, the rent of the stations, and other expenses, in return for which they would be worked and kept in order by volunteers who would find their own uniforms, and have a station constantly on duty, night and day, at all stations, so as to be ready to run out to a fire the moment a call is received. It cannot, I should think, be urged for a moment that such money would be badly applied, or that government ought not to grant funds for this purpose. The same plan might be adopted in regard to the engines and plant, as is followed when cannon, rifles, &c., are served out to the volunteers, but they should be commanded by their own officers, who should be paid out of the funds of the corps, and devote their whole time to the business; and except that the property of the engines and appliances would be vested in the Government, the whole should be, and be strictly maintained as, a volunteer undertaking in all respects.

If we take the rapid progress made by the volunteers in their drill and exercise as a criterion of what can be done by them when they take a thing in hand, we have every reason to believe that we should soon have a large number of most efficient firemen; for after all, the controlling and extinguishing of fires is a far more common sense proceeding than it is generally believed to be; and if it is possible to make ten skilled firemen, then it is equally possible to make one hundred or one thousand, especially where one has the common sense and intelligence invariably found in volunteers to deal with, and let Government give a grant to supply and maintain the stations and plant, and we will soon show them what can be done in the way of making a truly Metropolitan Fire Brigade.

As to the success of such an undertaking, let us take the Royal Society for the Protection of Life from Fire—and a more invaluable society scarcely exists—which we find is entirely supported by voluntary contributions (of more than £10,000 per annum), and the men who attend the escapes are actuated by the volunteer spirit, or they could scarcely perform the meritorious actions we so constantly hear of their doing, did they only work for their pay. If such a society as this, whose importance and advantages we all of us freely admit, can be supported by voluntary contributions, we surely cannot for a moment say that such an important and valuable institution as the Volunteer Fire Brigades cannot be equally supported.

I appeal to all, ladies and gentlemen, small and great, for a hearty and willing support, in return for which they will be amply protected from the dangers of fire by the Volunteer Fire Brigades, and also have the satisfaction of knowing that they have thereby assisted in enabling protection to be brought near to others, who otherwise might never obtain it.

We are one and all equally interested in carrying out this institution, as we shall otherwise have but one course open, namely, to pay heavy rates for the protection of endangered property owned by commercial men; but by supporting the Volunteers, it is not too much to say that under good and efficient management, and with a proper system to work on, her Majesty's Govern-

ment would look with a favourable eye on them, and encourage them as they did the Volunteer Riflemen.

There are two old proverbs, which apply with peculiar force and aptitude to the question of the proper and efficient mode of protecting London from the ravages of fire. The first is, "If a thing is to be done well, do it yourself;" and the second is, "What is everybody's business is nobody's business."

As an exemplification of how well a thing can be done when we do it ourselves, look at our volunteer riflemen, and the manner in which they have sprung up, learned their duties, and become a most important and efficient safeguard to the honour and power of the nation; and this, too, in spite of every prognostication to the contrary.

Let us, I say, have another example—in our volunteer firemen—of the truth of this proverb. Let us say we will, and assist to the best of our ability, and by our purse, our influence, and our time, those who are willing to take the labour and trouble of starting the movement, and putting it into shape, and the rapidity and certainty with which the system will be established cannot fail to be surprising and gratifying to all who have put their shoulders to the wheel.

The truth of the next proverb is most amply proved by the fact, that up to the present time we find no one has taken the subject up in the manner which its importance demands; nor has anything been done, except in isolated cases, to extend the means of controlling the London fires. It is evident from this that "everybody" is "nobody;" it remains, therefore, for us to eliminate "nobody" from the mass, in order to change this state of things; and if we leave "nobody" out of the calculation, and "everybody" will help "somebody," I shall have pleasure in taking his duties upon me, feeling sure that "nobody" will object to "everybody" doing his best to carry out the movement, and aid it to the best of their ability, and in concluding the paper I have just had the honour of reading, I will remind you of the appropriate words of the immortal Nelson, that "England expects that every man will do his duty."

DISCUSSION.

Mr. WENNER, whilst admitting the necessity of some additional means for the suppression of fires, could not concur in the suggestions offered in the paper just read. Some years since he visited America, and one night, in New York, he was awoken by the loud ringing of a large bell. On inquiring the cause of the disturbance, he was informed that it arose from one of the public fire establishments. With regard to the volunteer system, he thought, if a thing was worth having at all it was worth paying for. He had not been in New York more than ten days, when a very disastrous and rapid fire broke out in the Broadway; and although it did not last more than about an hour, no fewer than fourteen people lost their lives at it, all the sufferers being members of the Volunteer Fire Brigade; and it was stated in one of the newspapers that the larger number of these volunteers were not present at the fire for the purpose of suppressing it, but only for the purpose of plunder. Another instance was mentioned of a disastrous fire that took place during a banquet, and which was said to have been occasioned wilfully, in order to give the volunteer firemen assembled at the banquet an opportunity of displaying their valour and skill. He did not for a moment suppose that anything of the kind would ever occur in this country, but he was merely stating what he had experienced in America; although at the same time he thought some almost equally objectionable results would arise here from relying entirely upon the volunteer principle in the suppression of fires. When that principle obtained in this country with regard to the police—for at one time every tradesman was a constable—they had nothing like so efficient a body of police as they had under the existing paid system. His

own opinion was that fire brigades, to be effective, must be paid for the services they rendered.

Mr. C. F. DENNER felt called upon by the remarks just made to speak out for his own country. He was a native of Boston, U.S., and he had been a volunteer fireman there; and as a member of that society for many years, he was glad of this opportunity of giving his testimony in favour of the principle advocated by Mr. Young. With respect to the slumbers of the last speaker having been broken by the ringing of a bell in the night, he would say it was a good thing that in America, where the houses were somewhat slightly built, that a bell should be rung in the streets as an alarm of fire. By the improved system of organization that now prevailed in Boston and other American cities, the call to a fire was made by telegraph to the various stations, and the engines were started off with their attendants in the shortest possible time. In all the large towns, hydrants were placed at suitable distances through the leading thoroughfares; and in the smaller towns there were reservoirs containing many thousand gallons of water ready for use in case of fire, and the suction hose of the engine had merely to be placed in the reservoir to be brought into immediate action. Each volunteer brigade was under the command of a superintendent, and the whole was under the control of the municipal authorities. The superior officers of the brigades were chosen by the corps themselves from amongst the most efficient members, and every night there were hundreds of men in every town ready to do duty, in case of fire, at a moment's warning. The engines and equipments were the property of the town, but they were committed to the keeping of the volunteer brigade, amongst whom a friendly rivalry existed in the decorations of their respective engines and apparatus. Some of the brigades took a pardonable pride in those decorations; and in some cases the ornaments on the engine were of a costly character. In one instance the pipe which discharged the water was of solid silver. At least once a month the brigade was assembled for the inspection of the engines and entire apparatus, as well as for practice; and connected with the corps were associations both of a literary and benevolent character. The necessity for the extension of this system in London was shown by the scanty organisation that at present existed. Mr. Young had shown them on the map how few volunteer fire brigades had been established, and how ill-provided were many parts distant from the centre of the regular brigade. With respect to his own locality, the further side of Hyde-park, such protection as existed in that quarter was due to Mr. Dunsford, who had raised a volunteer brigade at Notting-hill. Within the last few years property to the amount of a million and a-half had been put up in that neighbourhood, and some of the buildings were erected with such slight materials that if a fire occurred at the bottom of the house it was almost certain to go right through the building in a very short time. He was a strong advocate for the volunteer system, but whether it could be carried out efficiently in this metropolis was a question for discussion. He thought the subject was of sufficient importance to warrant the appointment of a commission to visit America and other parts of the world in order to see their systems, and whether anything of value could be derived from them applicable to the case of the metropolis. As an Anglo-American, he had often been struck with the total insufficiency of the fire establishment in London, and it behoved them to adopt a more efficient mode than at present existed for protecting themselves and their property from the dangers of fire.

Dr. BACHHOFFNER thought there could be but one opinion as to the extremely inefficient state of the fire departments of the metropolis, but whether the volunteer system would meet the difficulty he was not prepared to say. With respect to the observations of Mr. Webber, he would only say that, though he was not prepared to gainsay his statements, he thought it was wrong to

condemn the system as a whole because there were some unworthy members in those brigades; he was, however, quite sure that such cases as had been mentioned would never occur in this country. With reference to government interference in this matter, the paper led them to believe that that idea had been abandoned; but he thought that was a mistake, and that the approaching session of Parliament would not close without a bill being introduced by the Government investing in the Metropolitan Board of Works the entire control of the fire establishments of London. Ably as the existing fire brigade was conducted, he thought the system was extremely unsatisfactory. Some, only, of the insurance offices contributed towards the maintenance of the regular fire brigade; moreover, the late Mr. Braidwood stated, in his evidence, that if a fire broke out at the British Museum, although it was known that building was uninsured, the brigade would attend that fire; but if another fire broke out at the same time in an insured building, they would leave the British Museum, and direct their efforts to the suppression of that fire. He had no doubt, if the project which was at one time entertained, of the amalgamation of the city and metropolitan police forces had been carried out, that measure would have been followed by the handing over of the fire department to the police, but there was difficulty in the way of doing that so long as two independent bodies of police existed. It was estimated that the cost of an efficient brigade would be £60,000 or £70,000 per annum, but from data in his possession he believed it would be nearer £160,000, of which amount it was estimated the parish of Marylebone would contribute about one-twelfth, which naturally induced the parishioners to set their faces against such a measure, particularly as there were in that parish two very efficient fire engines. He thought there was something radically wrong in the present system of attempting to extinguish fires; the volume of water thrown on was not sufficiently large. Attention should therefore be directed to the furnishing of some means by which a larger amount of water could be thrown into a burning building. With regard to the volunteer brigade movement, he wished it every success.

Mr. CLARKSON considered that greater attention should be paid to the prevention of fires, by having properly-constructed buildings, and also the providing of means whereby a fire could be acted upon immediately it was discovered. When a fire took place in Paris there was seldom more than a room burnt out. Owing to the careless manner in which lights were used in large warehouses it was not surprising that fires were of frequent occurrence; and he considered that the great preventive of extensive conflagrations was not in the number and efficiency of the fire brigades, but in the ready means of attacking a fire within the buildings in which it occurred.

Mr. PAYNE would be the last person to find fault with the London Fire Brigade, but the fact was they were totally inadequate in number and appliances to the work which was assigned to them. Moreover, the report of the surgeon of the brigade proved that a large amount of sickness existed amongst the men, caused by the overwork which they had to perform. The great point to be considered was the means by which a more adequate system could be established, and in whose hands the control of that department should be placed. If under the Board of Works, the taxation would be specially heavy; if under the police, their present duties would be neglected. With these considerations he thought the only quarter to which they could look for a remedy was the volunteer system. He trusted the time was not far distant when not only the metropolis, but every town in the kingdom, would have volunteer fire brigades.

Mr. WALTER NEWALL thought nothing should be laid in disparagement of the existing fire brigade of the metropolis. The late Mr. Braidwood and Capt. Shaw had shown what could be done with the very limited means at their command. Taking the extent of London as

ng and 9 miles wide, that gave an area of square miles, instead of 700 as stated in the which the operations of the Fire Brigade

The insurance offices having shown a lieve themselves of the burden of maintain-igade, the proposition might, perhaps, take that government should contribute one-third; the ratepayers one-third; and the insurance hird. A rate of a penny in the pound ex- the metropolis would produce upwards of Having been for a long time connected with stration of the building acts, he had arrived lusion that greater attention should be paid to ction of houses, particularly as regarded party eat security also resulted from maintaining a esure of water in the street mains, so that a r 60 feet high could be directed upon a fire at at of its discovery, and before the engines the spot.

H. DALTON, as a member of the Board of gged to say a few words on behalf of that body. state, in the first instance, that they had done laterver to seek the control of the fire brigade. sument had asked them whether they would that duty, and, as a municipal body, they felt t not to refuse it. For his own part, he could l no desire to share in that additional responsi- t if the Government and Parliament thought e undertaken by them, they could not do other- accept it. It happened that only a certain f the insurance offices contributed towards the ice of the fire brigade, while others refused to hose who did contribute felt it a burden upon l were not disposed to continue their contribu- hen this subject was brought before the Board, the opinion was generally expressed by the that, inasmuch as the insurance offices made fits out of their business, they ought to con- share to the cost; and that Government, having blic buildings, should also largely contribute. ference to the Association for the Protection of a Fire, he would say, although the funds were y voluntary subscriptions, the men who conducted -escapes were not volunteers, but were regularly their services, and in the event of the control of e Brigade being placed in the hands of the Board the association he had alluded to had requested e undertake the control of that business also. As far volunteer brigade system had gone, it had been ficient, but the brigades had been to a great extent led by men of large means, who had valuable fies of their own to protect. For his own part, ver, if the work could be done efficiently by volun- he would rather see it in their hands than in those in Board of Works.

L. A. BREWSTER HARRISON said having been in New t, St. Louis, Chicago, and New Orleans, he could state b equal to volunteer fire brigades that whereas in he they were drawn from what was termed the mible class, in New Orleans and Chicago they were n from the lowest classes of the labouring population. results were such as had been alluded to by Mr. der, for at a fire in Chicago he had himself seen men ed in rifling chests of preserved ginger instead of ing to put out the fire. In this country, however, it t be assumed that the volunteer fire brigades would zers from the respectable classes of the community, would render as efficient services as he had seen red by brigades of that character in New York and e. He agreed with a previous speaker, that the point was to have means at hand of attacking a fire moment it was discovered, as a quarter of an hour the outbreak tons of water would be of little use in nishing it. It was a fallacy to say that insurance d the losses by fire. They were simply spread he shoulders of the many, but there was the

actual destruction of so much property, which tended to enhance prices, so that the loss fell upon the public generally, and heaviest on the poorer classes of the com-munity.

Mr. T. JONES remarked that it was evidently intended, from the course of legislation on this subject, that there should be a volunteer fire brigade in every parish, because it was enacted that in every parish a fire-engine and ladders should be provided, which implied that there should be persons to work them, but it was no part of the law that they should be so small as to be comparatively useless. He thought it would be quite competent for parishes to organise a proper fire establishment within each paying district, and these, with volunteers in addition, would form the *nucleus* of efficient brigades through-out the metropolis and provincial towns.

Mr. S. TEULON said it was impossible to discuss the question of protection from fire in a city like London without feeling it was one of the most important subjects that could occupy their attention. It had been stated that unless water was applied at a very early stage of a fire it was very little use applying it at all, and, therefore, it occurred to him that the readiest mode of obtaining a supply of water to be directed upon a fire would be from high pressure in the street mains, with a hydrant placed at the bottom of each lamp-post. Objections had been made to employing the services of the police in this work. He would have them trained to the use of the hose, so that a fire might be attacked at once from the hydrants; but when the trained firemen arrived they should give way to them, and simply take the duty of keeping off the crowd. With reference to the volunteer system in this country, there was no doubt that, as regarded the rifle corps, it had been a great success, but the secret of that success consisted in the government having placed the highest officers in the regular army at the head of that force; so in the case of volunteer firemen, there must be an organized authority to which all parties must bow. They read in the history of the Great Fire of London, that the King deemed it his duty, as the chief authority of the kingdom, to attend personally and do what he could to mitigate the evils of that great conflagration. The custom prevailed very generally throughout the continent for the chief authorities of a town to give their attendance at fires. It was especially the case in Sweden. He (Mr. Teulon) was present at the fire which destroyed nearly one-third of the City of Gottenburg, where the exertions to subdue the flames were encouraged by the presence of the leading authorities of the place. It was the case also in Switzer-land. In Sweden, it was customary for alarms of fire to be given by a watchman, stationed on a steeple or other high building, blowing a loud blast from a trumpet, by which the inhabitants were summoned to give their aid.

Mr. COX (of the Holloway Volunteer Brigade) said, having been for many years a volunteer fireman, both in Australia and in this country, he was of opinion, judging from his own experience, that the brigades required no other head than that which was universally recognised in the captain of the brigade, in whose judgment and experi-ence the men had confidence. He could bear his personal testimony to the excellent working of the volunteer bri-gade system in Australia. His experience was that water would not always stop a fire, and that in many cases the most effectual check would be given by pulling down buildings in advance of the direction in which the flames tended. In such operations the services of the "hook and ladder" corps were very prominent, as he had himself seen in a great fire at Ballarat. He expressed himself highly favourable to hydrants in the streets, a system that was carried out in Melbourne through all the principal thoroughfares, at distances of 200 yards. He had the highest opinion of the value of the volunteer fire brigade system.

Mr. ROBERTS (True Blue, Millwall Brigade), as an old volunteer, would say a few words on this subject. With

regard to the strictly self-supporting system advocated by Mr. Young, that gentleman forgot that the supplying of their uniform at their own cost, with other expenses, involved considerable sacrifice on the part of the working men who formed the majority of the brigades; and, speaking with some experience, he was afraid, after a few years, the brigades would not find the subscriptions come in so readily as they did at first. With respect to the brigade of which he was the head, he could state that they had not received a penny from anyone for their services. In reply to what had fallen from Mr. Webber, he would say, better the slumbers of a whole town should be disturbed by the ringing of bells than that one life should be lost by fire. As to the method of attacking a fire, he was old enough in the service not to study show in such matters. It might be a tempting opportunity for a new brigade to show how high their engine would throw the water. His rule, however, was to "fire low," and attack the fire from the bottom. With regard to the best means of protecting buildings from fire, he confessed he had very little faith in the experiments that had been made with gases and salts as fire-annihilators. If they had those matters at hand the moment a fire broke forth they might put it out, but when fire had got hold, such appliances were of little or no use. As to the police having to do with fires he strongly objected to it, and the most essential service they could render was in keeping back the crowd. The chief difficulty on arriving at a fire was to get the engines at work, and on some occasions he had been obliged to clear the way by knocking people down. He agreed with the opinions expressed that the brigades should have some recognised head. He should be glad to see the volunteer brigade system extended throughout the country, and he hoped before long to see an Act of Parliament making it compulsory upon all parishes where a brigade was established, to provide sufficient engines and apparatus. He was sure there would be no lack of men to work them.

Mr. G. F. Wilson, F.R.S., said, having had opportunities of witnessing the working of the brigade which stood second on Mr. Young's list, established in 1844, he was bound to say, moving as this brigade did within a rather limited area, it had experienced no difficulties whatever, either with the London Fire Brigade or the police, and on occasions when they had co-operated with the former, they spoke in the highest terms of the assistance they received from them. Therefore he was disposed to think that, with harmonious action between the volunteers and the regular brigade, a most valuable aid would be afforded to their present means of combating fires in the metropolis.

After a few words from Mr. WENTWORTH SCOTT,

THE CHAIRMAN said, before calling on the meeting to pass a vote of thanks to Mr. Young for the paper with which he had favoured them, he would remark that they ought, before they decided as to what was the best course to pursue, to think of how gradually the present system had grown up, until it had arrived at a point where it appeared to have become necessary that there should be some general organisation for controlling the ravages of fire. Originally each parish was bound to provide engine-power, and the voluntary services of people were looked to to work that power, and it might be said that the new system advocated by Mr. Young was only an extension of this principle. From the vast amount of property accumulated, and the great increase of buildings, the existing system had become inadequate, and he hoped, if a return to the voluntary principle was made, this would be done in such a manner as to be most useful to the public. Some years since the parishes having been found wanting, both as to mechanical power and volunteer force, there arose the interference of the insurance companies; and undoubtedly, if they were to have an unauthorised body, without public responsibility, they could not organize a force which had so much inducement to do its duty as one employed by the offices who would have to

pay the damage done by the fire. To them it was a duty undoubtedly. Generally speaking, they performed it efficiently, but they found they were now in this position, that so vast was the extension of property, and so large an amount of it was not insured, that when two or more fires occurred at the same time, it was doubtful whether the uninsured would not be neglected for the sake of the insured property. They then came to two proposals, which might be considered together. The first was to place the control of this matter in the hands of the Government, and the second was to entrust it entirely to a volunteer body. They must, he thought, feel a strong objection to giving this power to the Government. He was one of those who thought the inhabitants of a municipality did what they required better for themselves than it could be done by the Government. But there was an important institution recently sprung up, the Metropolitan Board of Works, which, notwithstanding the disparaging remarks that were often made, was discharging its duties with great ability, and to whom it was proposed to entrust the management of these affairs. The question was, would that be more efficient than the volunteer system? The merits and demerits of that system had been thoroughly stated by the veteran volunteer from Millwall. He had said the volunteer brigade, while it was a novelty, was well supported, but now he found that support begin to flag. Some pecuniary aid appeared to be called for, and some authorised head under whose guidance the whole should work. Placing the volunteer fire brigade in comparison with the military volunteers, they both began much in the same way. The rifle movement was, in the first instance, carried on solely at the expense of those who volunteered; but it would not have remained as efficient as it is now if the Government had not interfered—first to place it under well-advised arrangements, and then to afford it such an amount of pecuniary assistance as enabled it to meet the difficulties which now appeared to arise in this other system. To a great many the cost of uniform would, no doubt, be very agreeable expenditure, but it might be different with many others whose services would be most valuable, and who might, from pecuniary considerations, be prevented from joining the corps. Looking at the manifest deficiency of the present system, he confessed he thought that a volunteer brigade, with a proper head (such as Captain Shaw, with whom should rest the appointment of subordinate officers), combined with a limited amount of pecuniary aid from the Government, would render very effectual service. He thought, however, that it was a mistake to suppose that the present fire brigade ever measured their work by the amount of their pay, or that any consideration of remuneration affected the willing discharge of the duties imposed upon them. They must all feel that the object was to improve an important institution of the country which had been neglected, and which he hoped the paper and discussion of that evening would tend to put before the public in a more satisfactory position than it had hitherto held. He was sure they would unite in a cordial vote of thanks to Mr. Young for having so ably introduced the subject to their notice.

The vote of thanks having been passed,

Mr. Young acknowledged the kind reception that had been accorded to his paper, and in reply upon the discussion, said he regretted that the remarks had wandered very much from the subject he had desired to introduce, viz., the difference between volunteer and paid brigades. The first speaker had spoken disparagingly of the "hook and ladder corps," but probably that gentleman was not aware that in Paris they used nothing but hooks and ladders, as was shown in a work published under the sanction of the Minister of War, entitled, "The Fireman's Manual." Dr. Bachhoffner had stated that only a certain number of insurance offices contributed to the brigade, but there were thirty who did so at the present time. He fully confirmed the statement of that gentleman as to the eff-

ciency of the fire arrangements in the parish of Marylebone. In reply to Mr. Newall, as to the area over which the London Brigade extended, he would state that they did not confine themselves to the metropolis, but they set themselves out to work over 700 square miles within and around London, even as far as Windsor, Dover, and Gravesend. With regard to fire-proof buildings, he denied that such a thing existed in practice, as was shown by the great fire in Gresham-street. Mr. Dalton stated that the Board of Works did not wish to have the control of the fire establishment; he was very glad to hear it, and hoped the unwished-for duty would never be thrust upon that body. Mr. Teulon approved of the interference of the police at fires. Their instructions were to hold the door and keep people out of the house, for which services they were paid a sovereign. He (Mr. Young) agreed that the volunteers should be organised under one head: he also concurred with the remarks of Mr. Roberts with respect to the cost of uniforms. With regard to the statement that there were fewer fires in Paris than in London, the last report showed that last year there were 1,899 fires in Paris, and only 1,624 in London. The serious fires in Paris during that period, however, amounted to only 570, and there were only 20 cases of total loss. Out of the 1,899 cases of fire about 1,300 were mere chimneys on fire. Of the fires in London 14 per cent. had been total losses. Without disparaging the services of the paid brigade, he preferred the volunteer system, for if a man put his soul into the work he would work better than one under compulsion.

Mr. STEWART HARRISON exhibited an arrangement for extinguishing fire in buildings at its commencement. It consisted of a reservoir and pipes, with valves at intervals throughout the building, so arranged that the valves are kept tight by plugs of fusible metal, and consequently, as soon as the temperature in any room reaches 212° , the plug is melted and the valve is opened, allowing of the escape of water. At the same time an electric circuit is completed, and alarm bells rung.

Proceedings of Institutions.

SOUTH AUSTRALIAN INSTITUTE.—The annual report for 1863-64, presented at the meeting held on October 11, 1864, states that a steady progress has been made in most of its important branches. The new Institute Act, which was referred to and its provisions explained at some length in the last report, was passed during the last session of Parliament. A meeting of the subscribers to the Library was held, as directed by the new Act, when, in December, 1863, J. P. Boucaut, Esq., was chosen to fill the office of Governor. Four quarterly soirées have taken place—the first in December, 1863, when the Rev. J. Maughan delivered a very interesting lecture on "Socrates, and the character of Athens in his time;" the second in March, 1864, when the Rev. Mr. Ibbetson lectured on "Natural Magic," with some curious illustrative experiments. The Lancashire Bellringers, at that time in the colony, were engaged for this soirée, and proved a great attraction. The third soirée was held on June 21, when the Lord Bishop of Adelaide presided, and the Hon. G. C. Hawker, M.P., who had shortly before returned from New Zealand, gave an account of his visit to that colony, and more especially to that part of it which is unfortunately the seat of war. The members of the Deutsche Liedertafel gave their valuable assistance in the musical part of this soirée. The last soirée took place on September 6, when His Excellency the Governor-in-Chief presided, and the Rev. Canon Russell delivered a very interesting and humorous dissertation on "Scottish Humour." The Christy Minstrels were engaged on this occasion. The following

lectures have been delivered since the last annual meeting, viz.:—"Oliver Cromwell," Rev. W. Hareus; "Colesridge," Rev. Canon Russell; "Mining in Cornwall," J. L. Young, Esq.; "Dr. Johnson," Rev. W. Hareus; "Geneva and Chamouni" (continuation of former lecture), Rev. F. W. Cox; "The Present Conflict in America," His Honour the Chief Justice; "Earth's Buried Cities—Herculaneum and Pompeii," Rev. J. Gardner; "Slavery—Ancient and Modern," the Lord Bishop of Adelaide; "The Circulation of the Blood," Dr. C. Clark; "The Marvels of the Solar Spectrum," Rev. J. Maughan; "Shakespeare's Jesters," J. H. Clark, Esq.; "The Solar Spectrum and its Teachings," Rev. J. Maughan; "The Progress of Music," H. F. Price, Esq. (with vocal illustrations by the Upper Hullah Class); "The Wonderful Properties of Matter" (illustrated by experiments), Rev. J. Maughan. As the last lecture of the spring series for 1863 would have fallen on Christmas Eve, it was thought that an evening of select readings might be more acceptable at that season than a lecture. This idea the kind assistance of several gentlemen enabled the Board to carry out very successfully, the Rev. J. Jefferis delivering a short introductory address on the occasion. A similar arrangement is proposed for the present year. The Institute Hullah Classes, under the direction of Mr. H. F. Price, have made satisfactory progress since the date of the last report. It is hoped that out of these classes, which are well attended, a permanent Choral Society in Adelaide will spring. Mr. Greffrath having left the colony at the end of 1863, the Board appointed Mr. Nootnagel as his successor in the mastership of the German Class, which, however, is not large. The French Class, which had for a considerable time only contained two or three pupils, has finally become extinct. The Board cannot but regret the indifference which appears to exist in reference to these two classes. The Drawing Classes are specially referred to in the report of the proceedings of the South Australian Society of Arts. The Board will therefore content themselves with expressing their satisfaction with the general tone of the instructor's report, although they could wish to see these classes also more generally supported. Four newly-formed country Institutes have been affiliated during the past year, viz.:—Mount Gambier, Moont, Mount Torrens, and Stockport; and two have suspended operations, viz.:—Port Elliot and Yankalilla. The former of these, however, is likely to be re-established before long. Efforts are being made in seven other localities for the establishment of Institutes, most if not all of which are likely to be successful. It sometimes happens no doubt that an Institute is established in a locality where there is not sufficient population to give it a fair chance for existence, and occasionally circumstances of a local and casual nature may lead to failure; but, as a general rule, it may be considered that when an Institute is once established in any locality both means and disposition will be found to keep it in existence; and if, through pressure of adverse circumstances, it should for a time fall into abeyance, it is pretty sure to be re-established before long. The total number of Institutes affiliated to the South Australian Institute and in active operation at the present time is 35. The following statistics of the total number of books, members, &c., of 33 of the country Institutes at the close of 1863 may not be without interest:—Books, 15,665; members, 1,473; income for year, exclusive of Government grant, £1,343. The arrangement for the delivery of lectures to country Institutes appears to give satisfaction, as the number of lectures delivered under it during the past year is greater than in either of the two preceding years during which it has been in operation; 45 lectures having been delivered at 21 Institutes between October 1, 1863, and September 30, 1864. Sub-reports of the proceedings of the Adelaide Philosophical Society and of the South Australian Society of Arts are attached to this report. It is not necessary, therefore, to refer further to those societies in this place.

Museum Department.—The sum of £250 was voted on the estimates for last year in aid of the Institute Museum. It was, however, specially voted for the augmentation of the Mineralogical Department only, and this restriction would have very materially checked the operations of the curator in other directions, had not the Hon. G. F. Angas offered a donation of £50 in aid of the Museum, on the condition that at least an equal sum should be contributed by the public. The sum of £64 was obtained, leaving, after necessary expenses were deducted, £57 to be added to Mr. Angas's donation. This increase to the funds available for the Museum has enabled the curator to make considerable additions to the various departments, more especially to that of ornithology. The vote has been partly expended in the purchase of a collection of minerals from Mr. E. R. Simpson, and of one of fossils from the Rev. J. E. T. Woods, of Penola; besides which the sum of £100 has been remitted to the Agent-General in London for the purchase of various minerals not in the Museum. These will be selected by Mr. Woodward, of the British Museum, with whom the curator has been in correspondence on the subject, and who has kindly promised his assistance in the matter. The annual report of the curator of the Museum gives full details on the various matters within his department.

Library Department.—In addressing themselves specially to the subscribers to the Library, the Board feel that they are called upon by duty and by sympathy with their bereaved Sovereign, and by affectionate remembrance of her departed Consort, mourned and beloved alike by herself and her people, to refer in the first place to the present which was received during the past year from Her Majesty the Queen, in the shape of a copy of "The Speeches and Addresses of the late Prince Consort," with presentation inscription and Her Majesty's autograph. As the most convenient mode of exhibiting Her Majesty's present to the public, it is for the time placed in one of the cases in the Museum. Eventually a suitable case will be procured, in order that it may be preserved in the Library, where it will doubtless ever be regarded as a most interesting and touching memorial. The "Mammals of Australia," recently published by Mr. Gould, in three volumes, has been received during the year, and, as well as the "Birds of Australia," mentioned in the last report, attracts much attention from visitors to the Library. The statistics of the Institute for the past year are as follows:—The number of volumes circulated during the year was 55,417. The number of volumes in the Library, as stated in the last report, not having been subjected to any deduction on account of books lost and worn out, for the reason therein assigned, it is of course useless to make any comparison of the respective figures at the beginning and end of the present year. The number of volumes at the annual examination, as already stated, was 12,077; add to this 121 volumes then missing but since returned gives 12,198 volumes at that date; 170 volumes of ordinary books and 151 volumes Patent Specifications have been added since the examination, making a total of 12,519. From this must be deducted 175 volumes presented to the hospital and lunatic asylum, which leaves 12,344 as the actual number of volumes in the Library at the present time. The total number of new subscriptions received during the year is as follows:—Quarterly, 218; annual, 42—total, 260. The actual number of subscribers on September 30 was, as nearly as could be estimated, 944. *Report of the Curator of the South Australian Museum on the progress of the Museum during the Year ending September 30, 1864.*—**Aves.**—The birds added to the collection since the last report amount to 250, which, in addition to the 200 mentioned in that report, now make 450 specimens, comprising 280 species of Australian birds, among which are many rare birds from the north-east coast and elsewhere, some of which have been procured by purchase and others by exchange.

Mammalia.—About a dozen specimens have been added, mostly small animals, natives of the colony. **Pisces.**—

Twenty different species of the fish of St. Vincent's Gulf have been presented to the Museum. **Reptilia.**—Numerous additions have been made, principally by exchanging with other museums. The collection now contains several hundred specimens in spirits, among which are many rare and some new species of our reptilia. **Insecta.**—A few specimens have been added from New South Wales, Western Australia, and elsewhere, and some cases of attractive insects from the Indian Archipelago have been kindly lent for exhibition by Mr. C. A. Wilson, and a large collection of Australian Buprestidae has also been lent by the Curator. **Mollusca.**—A small collection of European land and freshwater shells, also a few Australian shells, have been added to the collection. **Crustacea.**—Donations of several small species of crabs, &c., have been made. **Mineralogy and Geology.**—Many donations have been made of South Australian minerals and fossils, and a small but choice collection of minerals has been purchased, consisting principally of our copper and other ores; also an interesting collection of tertiary fossils from various localities has been purchased, consisting of about two thousand specimens and comprising seven hundred species. **Coins.**—A few coins, among which are some of great rarity, have been presented. **Miscellaneous Articles.**—A large assortment of native mats and other objects of native manufacture have been presented by Mr. George Taplin, of Point Macleay, and several similar objects by Messrs. G. B. and S. Yeates, of Brisbane; also some native weapons, from South Africa, by Mr. C. B. Jacobs. *Abstract of Proceedings of the South Australian Society of Arts.*—In reviewing the doings of the Society for the past year, it may be mentioned that, in pursuance of the plan of quarterly lectures, the first (on "Sculpture") was delivered by his Lordship the Bishop; the next (upon "Engraving") by L. J. Pelham, Esq. Unfortunately, from various causes, these lectures were very poorly attended; and it is suggested that it would be better to make similar lectures form part of the Institute course, or to reserve them until the Exhibition is open. The seventh Annual Exhibition was opened on the 1st December, in the rooms of the Institute, and comprised about 400 works of art. It remained open 27 days, and the total attendance was 2,793 persons. Some days were made free days, and on one of these (the day after Christmas) the attendance was 970 persons. The artists' prize list numbered 24, and amounted to the sum of £76 13s., of which 16 prizes were awarded—there being no competition for the others—and two special prizes were given. The names of the successful artists are G. Hamilton, A. Hunt, C. B. Labatt, J. Macgeorge, C. W. May, R. E. Minchin, J. D. Stone, E. Tomkinson, T. Ward, and E. M. Wilson. The distribution of Art Union prizes took place on the 30th December—the chair being taken by the Hon. John Hart, M.P.—and prizes to the value of £120 were distributed amongst the subscribers. During the Exhibition his lordship the Bishop and Mr. Pelham repeated their respective lectures to numerous and attentive auditories. Subjoined is the report of Mr. Hill, Master of the School of Design:—"I have the honour to report that for the year 1864 the progress of the pupils of the School of Design has been very satisfactory, but a great want of new models is felt, especially by the more advanced pupils. I trust the Society will soon be in a position to supply this desideratum. The total attendance for the nine months of 1864 was 30 students, of whom 14 were male students and 16 female students, and the maximum monthly attendance was 17, while the minimum was 13. The attendance was more equal than formerly. The branches of study were apportioned in the following manner:—From the flat, including outline, 8 pupils; drawing in colours, 5; mechanical and geometrical drawing, 5; drawing from the round, 4; drawing from nature, 4; free-hand drawing, 3; design, 1; total, 30." *Abstract of Proceedings of the Adelaide Philosophical Society.*—At the monthly meetings held during the year papers have been

read in the following order:—C. A. Wilson, Esq., on "The Entomology of the East Indian Archipelago and Southern Africa;" His Honour the Chief Justice, on "The Relation of Science and Theology;" Rev. J. Maughan, on "The Microscope;" George Windsor Earl, Esq., F.A.S., on "Artificial Shell Mounds;" Robert Kay, Esq., on "Ingenious Solutions of Mechanical Problems, as exemplified in Sir William Armstrong's Hydraulic Machinery and in Nasmyth's Direct-Action Steam Hammer;" O. A. Wilson, Esq., on "Wood-eating Insects;" B. H. Babbage, Esq., on "The Vital Statistics of South Australia." At the October meeting Dr. Muecke, of Tanunda, exhibited his valuable microscopic sections of Australian woods, at the same time giving much interesting information of a scientific character. The desirability of adding to the library some of the volumes of the "Royal Society's Transactions" and other issues of a kindred character, having frequently been urged by several of the members, it has been resolved to spend, under the direction of the Council, about £50 in standard books bearing on science and philosophy. During the year several new members have been elected, and several valuable reports and scientific papers, received from the neighbouring colonies and Great Britain, have been laid before the Society. In March last a very successful microscopic *soirée* was held—His Excellency the President in the chair—when a large attendance of ladies and gentlemen was secured, and a pleasant evening spent in examining a number of valuable microscopes, diagrams, and books kindly lent for the occasion by the members and other gentlemen interested in science. At this meeting his honour the Chief Justice, on behalf of the Philosophical Society, presented a beautiful and complete photographic apparatus to John Howard Clark, Esq., in acknowledgment of unwearied and valuable services rendered by him during the period of his secretaryship.

DUBLIN INTERNATIONAL EXHIBITION.

Great preparations are already being made by the Executive Committee for the musical part of the opening ceremony, on the 9th May. The orchestra will be arranged after the model of the one at Birmingham. The organ, which will be very large and complete, is building by Messrs. W. Hill and Son, of London. The number of performers will reach 1,000, and the whole will be under the direction of Mr. Joseph Robinson. It is intended to make the music, on this occasion, as great a success as it was at the opening of the first Irish Industrial Exhibition at Dublin, on the 12th May, 1853. Vocalists are to be invited and selected from the choirs in Liverpool, Manchester, Bradford, Leeds, Birmingham, and other towns and districts within easy travelling distance of Dublin.

Manufactures.

OPERATIVE COACHMAKERS' INDUSTRIAL EXHIBITION.—

This Exhibition, which is to be held in the Corporate Hall of the Worshipful Company of Coach and Harness Makers, Noble-street, St Martin's-le-Grand, will be publicly opened on Wednesday, February 1st, by the Marquis of Lansdowne, who is expected to arrive at noon. An address from the Committee of Management will then be read to the chairman of the day, and the Very Rev. H. H. Milman, D.D., Dean of St. Paul's, will offer up a Prayer. An anthem will be performed by amateurs, being coach operatives; at the conclusion of which the chairman will declare the Exhibition open. The amateur singers have kindly offered to sing again during the evening, and occasionally each week during the time the exhibition is open. By permission of Lieut.-Col. Lord Truro, a Guard of Honour of the 4th Middlesex (West London) Rifle Volunteers (Coachmakers' Companies) will attend, under the command of Captain Woodall. The

prizes offered by the Society of Arts, the Coachmakers' Company, and others, will be awarded by the following judges:—The Marquis of Lansdowne, Viscount Torrington, Mr. R. O. Mansell, of the carriage department, South-Eastern Railway, and Messrs. Hall, Rock, and Large. The first three were appointed by the Council of the Society of Arts, and the rest by the Coachmakers' Company.

Commerce.

SUGAR IN SPAIN.—Mr. Consul Marks, in his report on the trade of Malaga, states that the cultivation of the sugar-cane and the crushing, manufacturing, and refining of its juice has increased rapidly during the last few years; all lands capable of irrigation are being converted into sugar-cane plantations within the range of the temperate sea-coast climate, or the provinces of Malaga, Granada, and Almeria, commencing at Marbella on the west coast, and reaching to Adra on the eastern side. The climate appears particularly favourable to its growth, and the canes in some districts reach the largest size attainable by this plant; modern appliances in machinery have given an impulse to this important branch of industry which promises a rapid increase in its production. Notwithstanding that Spain has been supplied with sugar from its rich colonies in the West Indies, there has been and there still exists a protecting duty of 74 reals the 100 kilos, or about 19s. per cwt., levied on all importations from her possessions, and more than double that amount if from foreign sources. It was expected, on the late revision of the Spanish commercial tariff, that this protective duty would have been reduced; but the representatives of the agriculturists and manufacturers of the sugar-growing districts succeeded in preventing this contemplated reduction, which was borne out by statistical information, showing the enormous increase of the national cane plantations and the extent of the capital invested in this twin source of national production and manufacture. In the year 1848 this branch of agriculture might have been considered so trifling as scarcely to deserve mention; but in the year 1862, the production of sugar-cane sent to the respective manufactories may be estimated as follows:—250,000 arrobas from Nerja, 180,000 from Frigiliana, 100,000 from Maro, 350,000 from Torrox, 700,000 from Velez, 800,000 from Malaga, 1,500,000 from Motril, 470,000 from Adra—total, 3,800,000 arrobas. Say about 4,000,000 arrobas, or 45,000 English tons, yielding about 15 per cent. of sugar, or about 6,750 tons of refined sugar. The fanga or acre of land yields about 2,000 arrobas of sugar cane, which, at 14 cuartos, or about 4d. per arroba=rls (vn.) 3.305; expenses of cultivation rls (vn.) 1,500; or about £20 per fanega clear profit to the manufacturer. 2,000 arrobas will produce about 120 arrobas of sugar, which, sold at rs (vn.) 80 each, amounts to rs (vn.) 3,600; from which are to be deducted for expenses, rs (vn.) 1,146; profit, rs (vn.) 2,454, or about £24 profit on the reduction to sugar of the 2,000 arrobas of cane. About 10,000 acres of irrigable land are occupied in the growth of the sugar-cane along the southern coast of the Province of Granada, and these ought to produce 5,400,000 arrobas of sugar-cane. Twenty sugar factories exist in the district before mentioned; eight are first-class establishments worked by steam on the modern system of refinery; the other twelve are on the old plan of refinery, by boiling in the open air. About 5,000,000 of reals, or £50,000, may be considered as the amount of capital invested in the agricultural growth of the cane, and about 40,000,000 reals, or £400,000, in the construction and machinery of the twenty factories and refineries, requiring about 20,000,000 of reals, or £200,000, floating capital to keep them in constant work. The great drawback offered by the French Government to the exporters of French sugars helps in some degree to keep down the profits of the Spanish manufacturer, the drawbacks paid

this year on exportations of sugar in France having greatly exceeded the amount received by the French customs on importations of foreign sugar; the introduction of the article into Spain from France amounts to 160,000 arrobas of 25 lbs. each, or 2,000 tons, the drawback enabling the French to undersell the Spanish refiner, although their sugars are amenable to the heavy import duty. Sugar has risen lately in price as much as 8s. the hundred-weight, owing to the failure of the crops in the East Indies creating a deficiency of about 50,000 tons; and to the crops of beetroot in Russia and Poland having likewise proved a failure. In the Havana little sugar remains in consequence of the quantities taken in America. The Brazilian crop being late, will be exposed to the habitual rains at the end of the year. In the West India islands the cane has suffered from a long drought. In the Mauritius and Reunion the deficit is estimated at from 30,000 to 35,000 tons. In Louisiana the yield is quite insignificant. The demands from America are calculated at from 30,000 to 85,000 tons. The beetroot in France is suffering from the attacks of a parasite known as the *uredo betæ*, the destructive effects of which have been increased by the dryness of the past season. The general opinion is that the crops this year will not exceed one-third of the average; while in Spain the lands availed of for the growth of the canes are mostly irrigated from sources little affected by the rainy or dry seasons, and thus the crops have generally been of a fair average production.

TRADE WITH AUSTRIA.—The Austrian Government has called upon all the Chambers of Commerce in that country to furnish reports containing the statistics of the trade with England since the Anglo-French Commercial Treaty came in force, the object being to ascertain what effect that Act has had on the imports from Austria into England, and what advantages might be derived from a similar treaty between the two last-named countries.

EXHIBITION OF FISHING TACKLE.—The authorities of Boulogne have decided on organising in the course of the present year an Exhibition like that which took place some time since at Amsterdam, of fishing tackle and utensils, and all kinds of instruments connected with the maritime industry of all nations.

FIND OF COAL IN MEXICO.—A deposit of coal of the best quality has, it is said, been discovered in the mountains of Itoluca, at the distance of thirty leagues from the city of Mexico, and of sixty from Acapulco. Another deposit was discovered some little time since in the district of Tlalcala.

Colonies.

GOLD IN TASMANIA.—For years past gold has been produced from Fingal in considerable quantities, by odd stragglers, rudely provided with means of searching for it,—yet never sufficiently to infect people with a gold-digging mania and produce a rush. The quartz reefs have been tested by imperfect machinery. They have always turned out more gold to the ton than many of the average reefs that pay well in Victoria; yet, strange to say, they have never been considered of sufficient importance to attract the attention of capitalists, by whom alone they can be profitably worked. The first reef worked by the original Fingal Quartz Mining Company was very paying, twenty, thirty, and forty ounces of the precious metal regularly once a week rewarding the workers for their labour and their research. Flushed with the success of these their primary efforts, it was determined by the original quartz miners to go to work upon a new and more extensive basis. The company was augmented—and its capital increased to £12,000. New machinery, of a most expensive quality, was obtained from Messrs. Russell and Co., the eminent machinists of New South Wales; and works were completed of a very

comprehensive character. But, strange to say, from the day of opening no gold was taken from the original reef of the Fingal Quartz Mining Company. This was caused through the machinery being of an imperfect and impracticable character. Since then little has been done to develop the undoubted gold-bearing quartz veins that exist near Fingal. The failure of the extensive company alluded to has so blighted the hopes of many of the Tasmanian colonists, that unless capitalists from the adjoining colonies proceed with the works, little will be done. During the late session of Parliament one of the members for Lannceston introduced the matter of the gold fields to the House of Assembly, and asked parliament to grant £2,000 for the purpose of engaging Mr. Hargraves, the eminent gold discoverer, to prospect the country. That hon. member was met by the remark, that there was an Act of Parliament in existence which offered a reward of £5,000 to the person who would indicate the whereabouts in Tasmania of a gold field that was capable of producing, and absolutely produced for twelve months, gold at the rate of 100 ozs. per week. And no member would second the proposition. It was however determined that if Mr. Hargraves would come to the colony they would endeavour to secure his services without government aid. Accordingly public meetings were held, and subscription lists opened, the public liberally responding to the call. When Mr. Hargraves landed in Tasmania, an extraordinary ovation awaited him. The whole country was rejoiced to think that at length, with the aid of the great gold prospector, the question that had so long agitated the public mind would be solved. A most influential deputation waited upon the ministry, and were informed that the Government were anxious and willing to assist them by every means in their power, and that they would place £1,000 at the disposal of the Committee, to be appropriated in the prospect of gold, provided Mr. Hargraves, after his preliminary observations, reported it was necessary. This liberality on the part of the Ministry has been everywhere received with the utmost satisfaction. Mr. Hargraves has departed to Fingal to commence operations.

Notes.

RAILWAY BRIDGE OVER THE SEINE.—The Western Railway of France is now constructing a short line to connect the town of Rouen directly with the Paris and Cherbourg Railway, and the work includes a bridge over the Seine near Elbeuf. This construction will be more than 650 feet long and eighteen feet wide, and will rest on five series of tubular cast-iron piles, with intervals of about 160 feet between them. The bridge itself has been constructed on the banks of the river, and is now being placed on the piles, the entire structure, 200 metres long, being pushed forward by means of very simple arrangements from one side of the river to the other. The operation was commenced some time since, when the end of the bridge rested on the third set of piles after eighteen hours work. The weight of the bridge is given at a thousand tons, and the movement was given by sixteen men. The bridge is the work of Messrs. Schneider and Co., of Creusot, who adopted the same method in the case of the viaducts of Fribourg, in Switzerland, of Romans, on the Isère, and of Saint-Just, on the Ardèche.

COLLEGE OF ORGANISTS.—A society under this name has been instituted for the purposes of improving the position, advancing the interests, and encouraging the skill—both in composition and performance—of all who follow the occupation of an organist; and in its sphere of operation is included lectures, concerts, prizes, opportunities for the interchange of opinions among organists, the granting certificates of merit, and such other means as may appear to the government for the time being as best calculated to further the objects of the institution.

CAB INDICATOR.—The French authorities have for a long time occupied themselves with plans for checking the distances as well as the time of public vehicles; the old system of *courses*, single journeys within the limits of the city, has ceased to be fairly applicable since the limits of Paris were extended to the fortifications; the uniform charge for a ride of twenty minutes (for there is now a minimum rate for a journey of not more than a quarter of an hour) and for one of an hour is clearly unjust both to the proprietors of vehicles and to the public, and the circumstances of the case demand a re-adjustment of the system. The municipal authorities of Paris have, therefore, urged the company to which the public carriages belong to use its utmost endeavours to find a means by which payment by distances may be regulated. Many attempts have been made without success, but a metre, invented by MM. Menley and Verdier, seems to hold out some promise, and three have been placed in cabs belonging to the company. This instrument has two faces, which indicate—First, the distance passed over; secondly, the time occupied in so doing; and thirdly, the stoppages, which are added to the distances at the rate of eight kilometres, rather less than five miles, an hour. Should this new metre be found to answer in practice, there will be no difficulty between the hirer and the driver, as the former may engage a carriage either by time or distance. But the apparatus attempts more than this; it contains a card, on which it marks all the *courses* made during the day, the time employed, and the number of kilometres paid for by the public, and consequently the sum which the driver has received. It is declared that all this has been accomplished, and, if so, there is no question that the application of the apparatus will soon become general; but unless the action of the metre is arrested when the carriage is moving, though unoccupied, the driver would stand charged with the distances passed over from and to the stations and the places where he takes up and puts down his fares. This cannot, however, have been overlooked, and it is to be hoped, for the sake of all concerned, that the problem may have been solved.

PHOTOGRAPHIC MAPS.—A map of the town of Grenoble and its environs, embracing twenty square kilometres, has been produced with the aid of the camera in a very short space of time. The immediate object in view is the obtaining correct topographical profiles for military purposes, and, consequently, the means of placing an attacking force comparatively out of the reach of danger, but maps showing the undulations of the land are of too evident utility to require any special application to illustrate their value. The map in question is made to a scale of one in five thousand, and was entirely produced in Paris from twenty-nine photographic views taken from eighteen different points, by Captain Javary. The stations selected were partly on one side of the river Isère, and partly on the other, and it is believed that not a single accident of the outline has been missed. The extreme elevation of the ground on the right bank of the river is more than three thousand feet. The shortest distance at which a view was taken was about a thousand yards, the greater part were at fifteen hundred yards, and some few as distant as four thousand five hundred. It is stated, on the authority of M. Laussedat, with whom the plan originated, that fitting of the levels is such as could not have been produced by any other known method of expeditious military reconnaissance. The views were taken by two lenses of different focal lengths, namely, one of 50 centimètres, the other of 27. The former was employed for tolerably large representations and objects at a distance, or where it was found necessary to take special notice of details, and the other, which took in a field of 60°, for the shorter distances. The photographic operations only occupied about sixty hours, and the subsequent preparation of the map two months.

Correspondence.

PROPELLING RAILWAY TRAINS ON LINES WITH FREQUENT STATIONS.—**SIR,**—The paper on this subject read on Wednesday, the 18th inst., and the discussion which followed, do not seem to go far towards a solution of the difficult question of the propulsion of underground railway trains. Mr. Barlow proposes the long-abandoned rope traction, on a new plan, which might be called the "cross-bow" system; while Dr. Bachhoffner would recommend what he calls the "tea-urn" principle, on a rather large scale; others, again, advise the adoption of what may be called the "Enterogaster" engine, which is not only to swallow its food and water, but to digest and consume its stomach also. Mr. Barlow's plan is undoubtedly practicable, though occasioning a certain waste of tractive power; but the great objection is that with rope traction the driver does not accompany the train, and this, therefore, will never become popular. The expense of Dr. Bachhoffner's recommendation would, if practicable, absorb the whole revenue of the company, and leave nothing for profit and repairs. Lastly, the engine that is to swallow its own breath and smoke would appear to be quite contrary to nature, and approaches somewhat to the character of that grand desideratum of patentees and inventors, the perpetual-motion machine. The professed object of these and other contrivances is to obviate the vitiation of the atmosphere of tunnels. Now, the air in the tunnels of the metropolitan lines is quite as pure and wholesome as the atmosphere above ground, as must be the case from the ends of the tunnels being open, the frequent air shafts, and rapid passage of the trains both ways. But those tunnels are subject to the inconvenience which attends all open-air trains in an equal if not greater degree, the intolerable and disgusting nuisance of the present system of brakes. The burning of the wooden chook on the iron wheel produces a sulphurous stench that is almost unbearable, even in the open air; and it is a singular fact that none of the contrivances of engineers and inventors tend at all to diminish this evil, but rather to increase it. There are only two practicable modes known to us at present of avoiding the necessity of carrying a coke furnace through the tunnels,—the vacuum system, originally invented by Mr. Vallance, of Brighton, of sucking the entire train, with its load, through the tunnel; and the compressed-air locomotive. Vallance's plan is essentially economical, as a two-inch vacuum is amply sufficient for the heaviest loaded train. Its durability is unquestionable, but it is scarcely adapted for repeated stoppages at short intervals. The compressed-air locomotive is perfect in every respect, and, therefore, deserves every attention from inventors and improvers. Common air may be compressed to any degree of density with facility and economy by means of the triple compound condenser. The portable reservoirs, or salamanders, can be taken out, and charged ones replaced, in far less time than taking in coke and water, not to mention raking the fire bars. The extraordinary lightness of the compressed-air locomotive cannot be allowed to be an objection, because the whole train of carriages may be lightened in the same proportion. The enormous quantity of iron and oak introduced in the manufacture of an ordinary railway train car is quite absurd when considered in reference to the load carried,—less than two tons,—a load that is carried on common roads in vans not a quarter the weight of a railway car. The standard objection to the compressed-air locomotive is the assertion that no salamander of practicable size would carry a train more than two or three hundred yards. But if that assertion be founded on fact, which is very doubtful, why are not our inventive powers directed to the improvement of the air locomotive, and the general lightening of the machinery and construction of railway trains? The obvious answer to this question is the formidable fact that change of system is abhorrent to the vested rights of patentees, holders of

immense stocks of moulding and other patterns, and the rolling stock of existing companies.—I remain, &c.,
HARRY W. REVELEY.

January 23rd.

PROPELLING TRAINS ON LINES WITH FREQUENT STATIONS.—SIR,—If I understand Mr. Barlow's meaning rightly—and I am by no means sure that I do—for, like the old Scottish lady, I feel "it is a sort o' presumption to onnerstan the meenister," his new proposition of working railways is by a sort of kick, or succession of kicks, to the train, not directly, as in the plan of Mr. Pilbrow, shown in the Exhibition of 1862, but indirectly through the agency of a rope, to be acted on by a steam-engine driving a pair of wheels to haul on the rope; or by Sir W. Armstrong's water column; or by some other means. But the essence of it is to put in practice the principle of the tennis or cricket ball—a sudden shock instead of a gradual movement. When we play at bowls, using the muscular force of the arm as a propeller, the bowl is a rigid block of wood, and takes no harm, because there is a gradual force applied. So also when we strike a billiard ball with a cue. But with the cricket bat or racket we use an elastic ball. With Mr. Barlow's huge bat, weighing forty tons, we must give a very powerful elastic recipient to the train, to elude the shock and prevent the breakage of the rope. We must also attain great skill in striking the blow, to be sure we drive the train-ball far enough. But even then there seems a difficulty. Mr. Barlow's objection to the locomotive is that it is gradual in attaining speed; but we can carry that speed on for any length of time when attained. On Mr. Barlow's system we are supposed to start with a given velocity, but that velocity goes on gradually decreasing, and unless there be a succession of batters, there would be the risk of stopping midway before arriving at a station. And for this Mr. Barlow's remedy is a supplementary locomotive, and of course rails for it to run on, and sidings to get out of the way. Experience in the use of ropes for traction rather points to the use of slow motion, to avoid breakage; but as Mr. Barlow aims at increased speed he will have to provide such an amount of elastic action to graduate the force as will seriously detract from his incipient speed. All that Mr. Barlow can gain is the saving of the dead weight of the locomotive; but, so far as we can discern, this will be more than counterbalanced by other disadvantages. It is true that there may be more in the scheme than we have yet perceived, but as Mr. Barlow has not shown us a specific mechanical plan, and the whole is a question of mechanical structure, and his explanations have not been remarkable for lucid clearness to common understandings, we must wait in patience for further information. Mr. Chubb is quite right in saying that "the motive power should accompany the train;" but whether, under the necessity of getting rid of noxious gases, this can be accomplished by external power generated and transferred to the machine, is still a problem, whether in the form of compressed springs, or air, or highly elastic steam. If external power is to be applied in the shape of haulage, the most promising is the exhaust system of Vallance, a variation of which is now being experimented on by Mr. Hammell. If wire saucers in the shape of sheaves were used to carry a rope in the tunnel, as on the Blackwall, the noise would be something fearful. Train resistance by gravity, mechanical friction, and atmospheric impediment in the tunnel, up the gradient of 1 in 100, is stated by Mr. Burnett to be 66 lbs. per ton. If this resistance could be reduced there would be more advantage than by Mr. Barlow's plan. Supposing the ordinary resistance up 1 in 100 to be 40 lbs. per ton, there is 26 lbs. surplus arising from atmospheric resistance and train friction, and it is worth while considering how far the latter may be reduced. Reducing resistance is equivalent to reducing the consumption of fuel and the production of noxious gas. Practically, so long as the Great Western and Great Northern are to run ordinary engines over the metro-

politan lines, the only question worth considering is, how to prevent the destruction of rails and tires.—I am, &c.,
W. BRIDGES ADAMS.

PETROLEUM AS STEAM FUEL.—SIR,—Much interest is still expressed by our naval authorities, and by others connected with steam navigation, as to the proposed use of petroleum as fuel; and there is such a desire for information on the subject by many who confess being unable to judge as to the merits of this project, though they fully appreciate the importance of any mode of improving or economizing the use of fuel and augmenting its efficacy in practice, that I should be obliged if you would allow me to make some comments upon the subject more especially in reference to the position it has now assumed. The data relating to the comparative calorific power, or heating capability of petroleum and of coal, which I have already referred to,* are not disputed by the advocates for the use of petroleum as fuel; on the contrary, they are adopted by them. So far, therefore, we are unanimous. But, in reply to the objection which I have urged on the ground of cost, they suggest that the price of petroleum might perhaps be reduced if it came to be used as fuel; and if not, they believe that the lower cost—£10 to £12 per ton—at which a material almost identical with petroleum may be obtained from coal, would admit of that being used for fuel. So far as the price of petroleum is concerned, I am disposed to consider any anticipation of a reduction in price extremely delusive; and in reference to the lower price of coal oil, it will be sufficient to say that it would merely render the substitution of that material for coal less disadvantageous than a similar use of petroleum, and that the comparison between these materials, as fuel, would still be considerably in favour of coal. But the chief argument in favour of using petroleum as fuel is, that this material admits of being used for that purpose, in a manner so much more advantageous than is possible in the case of coal, that the disproportion in the cost of the two materials would be more than counterbalanced. They contend, also, that the relative advantages of petroleum and of coal cannot be determined by theoretical considerations, relating to the respective heating capabilities of these materials, and that they must be measured by the effects which can be produced in the two cases. In fact, the subject must be considered practically, and not theoretically. With this view I fully concur, and for that reason I regret that no practical evidence of the comparative effects or duty obtainable with petroleum and with coal, has yet been brought forward. It was only from the want of such practical evidence that I was led to have recourse to a theoretical consideration of the relative heating capabilities of petroleum and of coal, as the only accessible criterion by which an opinion could be arrived at as to the very startling statement that a ton of petroleum is equal to five tons of coal as fuel, and by which the wonderfully erroneous nature of that statement could be rendered apparent. It would have been far more satisfactory to myself to have based my opinion upon the results of trustworthy experiments, representing the actual duty obtained with petroleum and with coal. Nor can I refrain from expressing my surprise that a statement so extraordinary as that I have referred to should have been put forward ostensibly as the result of experiments in the Government Dockyard, with an appearance of authority which it acquires from the mode in which it has been made public, and without a vestige of practical evidence to support it. This is indeed the more remarkable from the fact that the advocates of petroleum appear to have been quite cognizant of the proper mode of instituting a practical comparison between different kinds of fuel. In the absence of such evidence, mere argument and assertion have but little value, and it is incumbent on those who have excited an interest in this subject to put their views to the test of experience, and either to substantiate them satisfactorily or acknowledge their error.

*See *Journal*, Vol. XII., p. 311.

But, in reference to the possibility of using petroleum as fuel more advantageously than coal, there is a means of instituting a practical comparison between them, which, in the absence of any more direct criterion, is deserving of notice. It is well known that no kind of fuel is burnt under ordinary circumstances so as to realise the whole of the heating effect it is capable of producing. The true comparison between different kinds of fuel is, therefore, not what they can do, but what they really do in practice. The actual work done by any kind of fuel depends partly upon its nature, partly also upon the kind of effect to be produced. When coal is burnt in smelting iron, for instance, the amount of its heating capability which is actually utilised, is not a tithe of that which is utilised when coal is burnt in an ordinary domestic grate; but in the one case the effect to be produced is the maintenance of an intense degree of heat; in the other, moderate warming only is required. In burning coal under the very unfavourable conditions which obtain in a marine-boiler furnace, experience has shown that there is a great difference in the duty or effect produced by equal quantities of different coals possessing equal heating capability. Hence the recognised practical superiority, for steam-vessels, of Welsh steam coal over the more bituminous kinds of coal represented by North Country coal. Now, what is the difference between these two kinds of coal to which their different value as steam fuel is referable? It is simply this; the Welsh coal is almost entirely fixed, approximating in this respect to pure carbon; it does not give out much combustible gas when heated, but it burns almost entirely within the furnace, and, unless the rate of combustion be very rapid, it burns completely, generating its full equivalent of heat, which is transferred, through the medium of the combustion products, to the water in the boiler. But bituminous coal, though of equal heating power, contains from 30 to 40 per cent. of volatilisable substance, and consequently, when heated, it evolves combustible vapour or gas to that extent; and this, mixing with the combustion products, is thereby rendered less readily combustible, and before it can be burnt it is drawn into the tubes of the boiler, where the flame is extinguished partly by the cooling of the gas and partly by the want of air, so that, instead of generating its equivalent of heat, it produces soot and smoke. This action takes place to some extent with all coal, especially when it is burnt under such unfavourable conditions as obtain in a marine-boiler furnace; but it is the degree in which it takes place that determines the relative value of different coals for steam navigation. The more a coal is capable of being burnt within the furnace the better it is for this purpose. The greater the amount of volatilisable substance it contains, the less suitable is it, and the greater is the extent to which production of soot and smoke is substituted for the production of heat; and, as these are correlative results, it follows that the fitness of coal for steam navigation is inversely proportionate to the amount of volatilisable substance it contains. At least this is, within certain limits, the case as regards the kind of boilers now in use. Applying this result of long experience to the case of petroleum, the conclusion which is leads to is even more disadvantageous for that material, as compared with coal, than the comparison of their theoretical capabilities; for petroleum is altogether volatilisable, and consequently it appears to me that there is nothing more incompatible with the use of petroleum as fuel than the conditions which obtain in a marine-boiler furnace. Doubtless it will be said in regard to this opinion that a peculiar boiler is contemplated for petroleum, but as to that nothing need be said until we are in possession of results indicating the evaporative effect attainable with petroleum as compared with coal. The signal misconception which characterises the views of those who advocate the substitution of petroleum for coal in steam navigation was most strikingly illustrated during the discussion which followed the papers read on this subject by Capt. Selwyn and Mr. Richardson, at the United

Service Institution; and to show the confusion of ideas prevailing on the important subject of fuel, I need only mention that Sir Edward Belcher referred to the oxyhydrogen flame, as proving the fuel value of hydrogen to be much greater than that of carbon or of coal. Nothing could possibly be more irrelevant, and it can only be inferred that Sir Edward Belcher is not aware that the thermal efficacy of the oxyhydrogen flame is solely due to the fact that oxygen gas is used in the place of air in the combustion. This circumstance alone places the case of the oxyhydrogen flame beyond the range of a practical consideration of the subject, and so far as comparison can be instituted between hydrogen and carbon when burnt with oxygen in place of air, the fact is that the thermal effect or temperature produced by carbon under that condition is far greater than that which is produced by hydrogen; these effects being in the ratio of about 10:7 for equal weights of carbon and of hydrogen. When these substances are burnt with air, the difference in thermal effect is inappreciable. Capt. Selwyn's reference to the common fish-tail burner used for illumination, and to the Bunsen burner used for heating, as being illustrative of the different effects obtainable by burning combustible substances under different conditions, was equally infelicitous; for in the flame of the fish-tail burner, and in that of the Bunsen burner, the heating effects produced are equal for equal quantities of gas burnt, and the thermal effects or temperatures produced are but little, if at all, different. The feasibility of the same gentleman's opinion as to the possibility of substituting coal oil for coal as steam fuel, may also be illustrated by the following simple consideration. Of the very richest oil-yielding Cannel coal—the Leeswood Cannel—about three tons are required to produce one ton of crude oil. In the production of this oil a considerable quantity of combustible gas, capable of generating a large quantity of heat, is lost, and there remains the greater part of the carbon of the coal in a state of coke, amounting to much more than one ton. So that the true fuel value of the oil from three tons of coal is really the fuel value of that quantity of coal, *minus* the fuel value of the coke and gas. Now, according to the representations made in favour of substituting coal oil for coal as fuel, one ton of oil is expected to do the work of five tons of coal; so that, according to this view, the fraction of the heating power belonging to the three tons of coal will be equal to the heating power of five tons of coal! This is equivalent to the proposition that half three is equal to five, and is comparable in absurdity with the wildest speculations concerning perpetual motion. That such a common-sense view of the subject should have escaped the perception of the gentlemen who propose to improve and economise the use of fuel, so as to bring about an entire reorganisation of our navy, and of steam navigation, is a fact which indicates a most woeful deficiency of acquaintance with the subject, and which well illustrates the proverbial danger of a "little knowledge." In conclusion, I would recommend the advocates of the use of petroleum to have recourse to that practical mode of deciding any question there may be in their minds as to the relative fuel value of petroleum and of coal, which I fully agree with them in thinking is the only satisfactory test, and which I have no doubt will bring them that conviction which is consistent with the real facts of the case.—I am, &c., B. H. PAUL.

8, Gray's Inn-square, Jan. 18.

HOT-AIR BLAST FROM COPPER INSTEAD OF FROM IRON TUBING.—**SIR,**—I have lately made some experiments, and think that hot air from copper will do good service in the manufacture of colonial sugar. 1st. By heating the cane in chambers so as to decrudify or unraw the whole; previous to crushing in the mill; the effects will be softening of the cane, and rendering it so as to give forth its juice devoid of admixture with glucose or such like, which causes decomposition to the juice, and necessitates the use of lime to temper or rectify such acidity, 2ndly. The hot air will do to force into juice in earthen-

ware pans, and so effect concentration without burning, as at present, with fire underneath vessels. Copper tubes are more ductile than iron, can be more readily mended, and never burst.—I am, &c., C. M. Dick, Sugar Planter, late of Trinidad.

Patents.

From Commissioners of Patents Journal, January 13th.

GRANTS OF PROVISIONAL PROTECTION.

- Power looms—3200—E. Fielding.
Pumps, ordinary lift and force—11—M. Benson.
Railway carriages, lamps for—3212—J. Parkinson.
Railways, communication between passengers and guards travelling on—3109—A. R. Croucher.
Railways, fastenings for—3233—M. A. Muir and J. Melliham.
Railways, girders for—3243—E. Shuttlebotham.
Railway trains, apparatus for signalling in—3227—W. H. Preece and A. Bedborough.
Railway trains, signalling between the passengers and the guard and driver of—3218—W. Buttum.
Railway wheels, construction and fitting of—3202—E. Leahy.
Rotative motive power—3247—E. Comprant.
Saws—3072—G. Rooper.
Ships, saving from sinking—3179—J. Smith.
Spectacle frames—2656—P. A. Le Comte de Fontainemoreau.
Stamping apparatus—3061—A. Albert.
Steel and iron, manufacture of—3073—J. Ramsbottom.
Tea-pots, coffee-pots, &c.—3206—T. Robinson.
Textile fabrics—3157—P. Cameron.
Umbrellas, &c., top notches and runners for—3220—H. Johnson.
Water, &c., apparatus for measuring—3145—C. W. Orford.
Yarns, mode of treating warped—3228—W. Holmes.

INVENTION WITH COMPLETE SPECIFICATION FILED.

- Ordinance, construction of—54—H. Ames.

From Commissioners of Patents Journal, January 20th.

GRANTS OF PROVISIONAL PROTECTION.

- Artificial fuel—81—D. Gattafent and F. Pontifex.
Artificial manure, manufacture of—3161—S. F. A. de Brocade d'Eliza.
Axles, apparatus for lubricating—6—J. Smith, jun., and J. Williamson.
Belt for ladies' wear—17—L. Goldberg.
Beverages, preparing and keeping aerated—39—T. Fickford.
Bones, extracting and purifying fats from—93—A. G. Lock.
Boots and shoes, shaping and trimming the heels of—49—G. Haseltine.
Bread, apparatus for making aerated—3184—R. L. Howard and J. Daughlish.
Bricks, manufacture of compressed—77—H. Chamberlain.
Carling engines—3253—J. Ladley.
Colour printing—3093—C. Hancock and S. W. Silver.
Cotton gins—2748—H. V. Scattergood.
Dentistry, painless—3229—J. D. Morrison.
Dyeing and printing, aniline colours for—3045—E. T. Hughes.
Eggs, keeping the substance of, fresh and sweet—47—W. C. Thurgar.
Enamelled glass, manufacture of—12—W. G. Helsby.

- Enamelled wares, manufacture of—3242—B. Baugh.
Fibrous materials, flyers for preparing—68—R. A. and G. H. Lightoller.
Fibrous materials, machinery for combing—3210—T. Whitley and J. Jowett.
Furnaces, &c.—51—J. Robertson.
Gas, carbonic acid—3192—A. P. Price.
Globes, geographical—3244—E. Perce.
Hair, apparatus for brushing—3246—A. C. Robb.
Hair, brushes for the—61—T. Horrex.
Horse shoes, machinery for making—3254—W. E. Newton.
Hydrometers—75—E. W. Ladd and L. Oerling.
Iron pipes, &c., apparatus for cutting—86—W. E. Gedge.
Jack and slubbing frames—63—A. Barlow.
Jewellery, &c., manufacture of cases for—3056—R. Quia.
Joints, cutting at one operation dovetail and mitre—3228—R. H. Leam.
Knives, cleansing and polishing—26—G. Kent.
Lint, manufacture of—13—S. S. Brown.
Liquids, apparatus for measuring—29—W. Payton.
Locomotive steam engines—3232—J. Millan.
Locomotive engines—35—J. E. Wilson.
Looms—43—J. A. Castree.
Mantures, manufacture of—3266—T. Richardson.
Mattress or bedstead, elastic—67—W. E. Gedge.
Meat, preservation of—79—T. B. Belgrave.
Motive power, obtaining and applying—3260—C. W. Siemens.
Ornamental fabrics, weaving—48—J. Craw and J. Macaulay.
Paper, machinery for smoothing or finishing—9—J. R. Crompton.
Perambulators—14—H. Lloyd.
Pictures, mounting—10—F. Gye.
Pistons, elastic packings for—19—E. Keirby.
Plates and strips of metal, machinery for slanging—3216—G. Allen.
Pneumatic apparatus—3230—G. Edwards.
Pneumatic apparatus, portable—16—T. J. Ashton.
Printing machinery—2263—W. E. Newton.
Projectiles—3240—R. Cail.
Railway carriages, construction of—95—R. Chidley.
Railway clerks, checking the receipts of—3218—W. H. Ray.
Ralls, reeling and furling—83—H. Coutanche.
Sewing machines—3238—J. H. Johnson.
Sewing machines—2—T. A. Macaulay.
Sheds, railway stations, &c., construction of roofs for—3250—T. Bouch.
Steam and heat, apparatus for generating—33—J. M. Kirby.
Steam boilers, foot for indicating the level of water in—3254—J. and W. Trussell.
Steam engines—3236—W. Nalder and A. Belcher.
Steam hammers—89—J. Ramsbottom.
Taps—67—J. Calkin.
Tubular boilers, construction of—37—J. C. Ames and W. Anderson.
Valves, &c., box for preserving—3154—W. E. Gedge.
Vessels, apparatus for propelling—29—W. Watson.
Volatile fluids, lamps for burning the vapour of—41—J. C. Bayley and D. Campbell.
Watches, construction of components for—53—G. Raymond.
Wood, preservation of—3192—J. Bethell.
Yarns, finishing cotton hedd and other doubled—3186—J. E. Edge and E. Hird.

Announcements by the Council.

CANTOR LECTURES.

The Second Course of Cantor Lectures will be "On the Applications of Geology to the Arts and Manufactures," by Professor D. T. ANSTED, M.A., F.R.S., and will be delivered on Monday evenings, at Eight o'clock, as follows:—

FEB. 6TH.—LECTURE 1.—On the Formation of Natural Soils by Derivation from Rocks, and on the Improvement of Soils by the admixture of Minerals.

FEB. 13TH.—LECTURE 2.—On Natural and Artificial Springs, and on the various Sources of Water Supply for Towns and Cities, in connection with the Geological Structure of the Vicinity.

FEB. 20TH.—LECTURE 3.—On Mineral Materials used for the Purposes of Construction: Plastic and Incoherent Materials (Clays and Sands).

FEB. 27TH.—LECTURE 4.—On Mineral Materials (continued): Building Stones and Slates, and their Relative Value under given Circumstances of Exposure, and on Methods of Quarrying.

MARCH 6TH.—LECTURE 5.—On Stratified Deposits of Minerals, as Coal and Iron Ore, usually obtained by Mining Operations, and on Mining Methods for such Deposits.

MARCH 13TH.—LECTURE 6.—On Metalliferous Veins or Lodes and their Contents, and on the Extraction of Metalliferous Minerals from Lodes.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture. For this purpose a set of Tickets has been sent to every member.

FINAL EXAMINATIONS—BOTANY.

In addition to the Prizes in this subject offered by the Society of Arts to candidates taking a Certificate of the First Class, the Royal Horticultural Society offers five prizes, of £5, £4, £3, £2, and £1 respectively, to the five candidates being gardeners by profession, who, taking

any grade of certificate in Botany, obtain the highest number of marks in that subject at the Final Examinations in April next.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

FEB. 8.—Adjourned discussion on Mr. J. C. Morton's paper "On London Sewage from the Agricultural Point of View."

FEB. 15.—"On the Claims of Authors and Inventors to Property in and Protection for Designs and Inventions first published at Industrial Exhibitions." By THOMAS WEBSTER, Esq., F.R.S.

Proceedings of the Society.

CANTOR LECTURES.

FIFTH LECTURE.—MONDAY, JAN. 30.

Mr. WATERHOUSE HAWKINS delivered the fifth and last of his course, on the "Reproduction of Natural Forms by Art and Manufactures," the subject of this fifth lecture being Ceramic Manufacture, with the influence of the material on the design, and its successful production; modern terra cotta, Della Robbia ware, Majolica, Palissy ware, and Faience. The metal casting (which at the conclusion of the previous lecture was not completed in time) was exhibited to the audience. The metal having been poured, the sand mould was knocked off, and the cast of an animal in bronze metal was shown, with "gets" or channels through which the molten metal had passed. The moulds for metal casting, being made of sand, were soft and destructible, so that a fresh mould had to be made for each cast, whereas the moulds for ceramic wares were hard, and the cast was drawn from them in a semi-plastic state. Figures in metal might be cast whole, whereas figures in ceramic material were cast in many pieces from separate moulds. Ceramic or pottery wares were amongst some of the most ancient art-works of man. In the days of the ancients, Homer, while on his travels, came to a pottery; the potters being (as were all Greeks), enthusiastic admirers of poetry, bargained with Homer to give him one of their finest vases as a recompense if he would recite to them some verses

in honour of their art. This the sublime poet thought it not beneath him to do; he sang in praise of their art for, though blind, he could appreciate the beauty of forms in their wares. In modern days, not many months ago, the classic eloquence of the Chancellor of the Exchequer, Mr. Gladstone, was called forth by the beauties of pottery and its artistic decoration. In speaking of majolica, we must call to mind the name of Raphael, who thought it not a condescension to devote his talents to the decoration of porcelain, but though his works in majolica were so admirable, the drawing so free and bold, untrammelled by an excess of finish or of colouring, yet the style of majolica was not so faultless as to be copied implicitly in the present day. The entire covering of an object of utility with a picture was not legitimate decoration. When a dessert plate, for instance, was entirely covered with a picture, it could not be used without so disfiguring it with the juice of fruit that it was no longer possible to appreciate its artistic beauties. With regard to the ware termed *Della Robbia*, it consisted of sculptured figures in clay covered with a coloured glaze; and in that known as *Palissy ware*—the most perfect reproduction of animal forms in pottery—the fish and reptiles in the centre of a dish or plate for soup, were at the time they were made regarded as practical jokes, and so life-like did the great artist, who was also a profound naturalist, make these reproductions, that when covered by a transparent fluid soup the delusion was complete; but now that the idea of their reality was not entertained, the copies and imitations of *Palissy ware* were of no avail, except as gratifying illustrations of the fact that whatever had been done in ceramic could now be repeated by our enterprising manufacturers. After mentioning the distinguished names of Wedgwood and Minton, of our own time, Mr. Hawkins recurred to the loss which manufacturers had sustained within the last few weeks by the death of Mr. Thomas Battam, who, by the union of practical knowledge with artistic skill and feeling, had done so much for ceramics, more especially for *Parian*. Mr. Hawkins next spoke of *terra-cotta*, which, by reason of its durability, afforded so many facilities for out-door decoration. *Terra-cotta* was first successfully manufactured in this country between the years 1790 and 1800, this enterprise being commenced by a lady of the name of Coade, at Lambeth, but it was for a time superseded by cement. In 1845, the manufacture was again revived by Pulham, of Broxbourne, and by Blanchard and Blashfield, of London. *Terra-cotta* presented so many advantages in its susceptibility of undercutting and relief after moulding and previous to fixing, and also in its suitability to our climate, being more durable and less affected by weather than even the best stone, that it was a subject for regret that our artists did not make more use of it. There was also another use to which it had been put, viz., as a material for portrait busts. In the South Kensington Museum there were several beautiful ancient busts in *terra-cotta*; and Mr. Hawkins showed his audience a plaster cast of a *terra-cotta* bust of Shakespeare, by Roubillac, which was discovered in the pulling down of a building in Lincoln's-inn. It was broken into pieces by the workmen, but after having been re-united by Mr. Clift, was moulded and cast by Mr. Hawkins, while engaged in his great works at the Crystal Palace. This bust presented many difficulties in moulding by reason of the deep undercuts, it being evidently the hand work of the artist, having never been intended for multiplication by casting, and hence the complications in which the modeller had indulged. "Modelling" for *terra-cotta* might more appropriately be termed carving, for modelling might be defined as putting on what was required, but carving was taking off from the surface and leaving what was required. If the artist, in providing a work for *terra-cotta* or any other ceramic ware, thoughtlessly added a piece of clay, according to the ordinary process of modelling, that piece would, in the firing, crack or come off. It was therefore a necessary condition for all works

leaving the artist's hand direct for the fire that the mass be homogeneous. Works in *terra-cotta* when moulded, were also divided into pieces for firing, like other ceramic works; the arms, for instance, of a figure were cut off, and the lower limbs also; the artist therefore must, in making a design, take this condition of the material into consideration, and by armlets on the arms, or by the edges of the drapery, aid in the concealment of the inevitable joins. *Parian* presented the same difficulty, as Mr. Hawkins demonstrated by sketching on his canvases the fourteen pieces into which a small *Parian* group, called the "Cat's Paw," of a monkey with the cat and chesnuts, which he had himself modelled many years ago, had been cut for moulding. The complexity of the design had thus increased the labour of the moulder—adding to the expense in production. Again, another difficulty of *Parian*, which was shared only in a slight degree by *terra-cotta*, was the contraction which took place in the drying and firing of the cast. To illustrate this, Mr. Hawkins had on the table two busts of the Prince of Wales, one in plaster and the other in *Parian*, both cast from the same mould, though the *Parian* was one-fourth smaller than the plaster cast. In slender parts, such as the limbs of a figure, the contraction was of course more rapid than that which took place in the bulk of the body. To guard against the possible deformity which this would occasion, the artist had to give additional size to the slender portions, that they might be compensated for, and the contraction become of due proportion with regard to the more solid parts of the figure. These and many other difficulties in material and process, if not known by the artist, would be insuperable obstacles to the reproduction of his works, whereas, if he had a thorough practical knowledge of them, he might so adapt his designs as to facilitate the operations of the workman, and thus that happy co-operation between artist and manufacturer would be secured without which works of art could not be so multiplied and perpetuated in connection with articles of utility as to increase their commercial value, and at the same time reduce the cost of production, so that the masses of the people might become familiar with the refining influence of true art, judiciously combined with the requirements of every-day life.

At the conclusion of the lecture, Mr. HAWKINS, who occupied the chair, rose, and after remarking on the amount of practical knowledge as well as artistic power which Mr. Waterhouse Hawkins had displayed in his lectures, and in his graphic illustrations on the black canvases, proposed a vote of thanks, which was most heartily responded to by the audience.

NINTH ORDINARY MEETING.

Wednesday, February 1st, 1865; EDWIN CHADWICK, Esq., C.B., in the chair.

The following candidates were proposed for election as members of the Society:—

Cockel, George, 77, Onslow-square, S.W.
Creswick, J. Frost, 8, Bloomsbury-square, W.C.
Evans, George, Newton Heath, Manchester.
Kirkman, C.F., 27, Claremont-terrace, Fentiman's-road, South Lambeth, S.
Mayson, J. S., Rusholme.
Morey, Samuel Dance, Ironmonger-lane, Chancery-lane, E.C.
Seymour, J. B. W., 28, St. Augustine-road, Camden New-town, N.W.
Telbin, William, 29, Winchester-crescent, Cheyne-walk, Chelsea, S.W.
Tetley, J. Birmingham, 21, Carlton-hill, N.W.
Tonge, George, 8, Lancaster-terrace, Upper Hyde Park-gardens, W.

The following candidates were balloted for and duly elected members of the Society:—

Beloe, Chas. H., 26, Bedford-place, Russell-square, W.C.

Bishop, James, 176, Upper Thames-street, E.C.
 Bowring, John, 51, St. Mary-axe, E.C.
 Dean, John M., The Grove, Stratford, E.
 Gibson, John, 1, Stamford-terrace, Stamford-hill, N.
 How, Thomas, 29, Gloucester-place, Hyde-park, W.
 Hughes, Joseph, 37, Queen-street, Ratcliff, E.
 Lavey, Charles, 341, City-road, E.C.
 Parker, George Bass, 25, Grove-terrace, Highgate, N.,
 and 4, King-street, Cheapside, E.C.
 Paty, General Sir George William, K.C.B., 24, Regent-
 street, S.W.
 Peard, Thomas, 159, High Holborn, W.C.
 Pendergast, John, 103, Adelaide-road, N.W.
 Pike, Fred., 44, Charing-cross, S.W., and Dulwich, S.E.
 Piman, William, 210, Euston-road, N.W., and 88, New-
 gate-street, E.C.
 Plowden, Trevor Chickell, Oriental Club, S.W.
 Plucknett, George, 258, Gray's-inn-road, W.C.
 Pratt, Hodgson, 8, Lancaster-terrace, Regent's-pk., N.W.
 Rejlander, O. G., 129, Malden-road, N.W.
 Robinson, Thomas, 260, Gray's-inn road, W.C.
 Roebuck, William, 21, Ellington-st., Arundel-square, N.
 Sconce, Gideon C., 43, Lincoln's-inn-fields, W.C.
 Sexton, George, M.D., 63, Springfield-road, St. John's-
 wood, N.W.
 Sharp, Henry Locker, 15, Great Cumberland-street, W.
 Shaw, Maltman Wm., 24, Carlton-hill-villas, Camden-
 road, N.W.
 Stanton, John, M.D., 9, Montagu-square, W.
 States, William, 12, Prince's-street, Hanover-square, W.
 Stevens, Henry, M.D., 78, Grosvenor-street, W.
 Stewart, Donald, 7, Gloucester-terrace, Regent's-park,
 N.W.
 Stuart, Charles, Manor-house, Stepney-causeway, E.
 Taylor, John Henry, The Limes, Upper Holloway, N.,
 and 15, South-street, Finsbury, E.C.
 Teape, Hannaniah, 37, Trinity-square, Tower-hill, E.C.
 Thomas, William, 20, Boltons, West Brompton, S.W.
 Thorold, Rev. Anthony Wilson, 16, Bedford-square, W.C.
 Vickers, Stanley, Hill-house, Streatham-common, S.
 Waller, Edmund, 217, Brompton-road, S.W.
 West, William Nowell, 30, Montague-street, Russell-
 square, W.C.
 Whytock, Alexander, 9, George-street, Edinburgh.

AND AS HONORARY CORRESPONDING MEMBER.

Honeyman, Rev. D., D.C.L., Antigonish, Nova Scotia.

The following Institutions have been received into Union since the last announcement:—

Dean Mills (near Bolton) Institute.
 Newton Heath and Failsworth Mechanics' Institution.
 Rusholme Public Hall and Library.

The Paper read was—

LONDON SEWAGE FROM THE AGRICULTURAL POINT OF VIEW.

By JOHN C. MORTON, Esq.

I am perfectly aware that any service to be rendered by the Society this evening towards the utilization of London sewage must depend principally upon the discussion which is to follow the reading of this paper. I shall, therefore, not occupy your time for long in stating, as an introduction to this discussion, the data and conditions on which agriculture may be able to offer a solution of the difficulties which surround the subject.

Early last November, before the Metropolitan Board of Works had decided what to do, and while the public papers, stirred up by the report of Lord Robert Montagu's committee, overflowed with controversy on the sewage question, I suggested to your Secretary that advantage should be taken of the agricultural week in December, when many farmers are in town, to submit some of the schemes which had been propounded before that committee to the test of such criticism as they would have re-

ceived here from an agricultural audience. The Wednesday in question had, however, already been allotted, and that is how the discussion happens to have been delayed till now, and left for me to introduce.

In this paper, then, on "London Sewage from the Agricultural point of view," I not only mean to exclude the engineering and sanitary aspects of the question, but, while discussing the merely agricultural aspect of it, I wish to confine myself and you to that view of it which it presents, not to ratepayers and enthusiasts, but to farmers. Of course everybody knows that there has been a great deal of wild enthusiasm and speculation excited by both newspapers and committees; and even agricultural journals have been "bitten." I suppose that if a sober view of the agricultural value of sewage manure were anywhere to be expected, it would have been in the columns of the *Mark Lane Express*. But what does the clever editor of that agricultural paper say? He declares that recent experiments, discussions, and discoveries have thrown so much new light upon it, and made us all so much more sanguine of a profitable issue, that an altogether new leaf in the book of agricultural progress has, in fact, been turned; and therefore, if any one shall hereafter quote any of the former leaves of this book—any of the older blue books, whether containing evidence of writings of his own or others—in any future discussion of the subject, a vat of the very richest of the stuff is to be prepared, and he is, in short, to be ducked in it.

Now having unfortunately given evidence before Dr. Brady's committee; and having, at intervals during several years, used what opportunities occurred to me of presenting the facts and stating the arguments which have year by year accumulated as the urgency of the question grew, it might thus be difficult for me to avoid the fate which my kind friend and brother editor had prepared for me. In order, therefore, both to escape the ducking, and also to give the most recent evidence of an eye-witness, avoiding all reference to blue books and other publications, I have within the last few weeks spent a day at Rugby, and another at Birmingham, a couple of days at the Craigentiny meadows near Edinburgh, and a couple of days at Croydon. Along with Mr. Harrison, M. Inst. C.E., of Forester Court, Gloucestershire, I have also spent a week in South Essex, down at the Dengie Flats, the Maplin sands, at Burnham, Foulness, Rayleigh, Stanford-le-Hope, and other places, trying to find out in what relation the present circumstances of Essex agriculture stand to the subject; and we paid visits to the home farm of the Earl of Essex at Cassiobury, and to Mr. Blackburn's farm at Aldershot. And I propose to-night to tell you what I have seen and heard within the last two months at all these places.

Of course the evidence of an eye-witness accustomed to the inspection of farms and to the examination and discussion of both ordinary and extraordinary agricultural experience, who has made it his business to examine afresh in this way almost all the places where sewage is now being utilised, must be a serviceable contribution to the discussion of the general subject, provided only that it be impartial. And if it be objected, as it may, by advocates of any of the schemes for using London sewage, that anyone who has already committed himself to a particular view of the subject, before, for instance, Dr. Brady's committee, must be pronounced already prejudiced and partial, then it must be at once admitted, that an acquaintance both with agriculture and with sewage had led me long ago to a definite opinion of the right way to connect the two; and that, having formed this opinion after a previous inspection of most of the places named, it was with some confidence in its soundness that I recently examined them again.

This I presume is what is meant by prejudice. Allow me to say that there is no word used by amateurs in agricultural discussions that is more maltreated and abused. Any one—I do not say a professional agricultural chemist who works almost as much in the field as in the laboratory,

but a man who takes his facts from the laboratory of the chemist, who deals with soils or with manures on filter papers, in bottles, and in crucibles, or with plants in fragments and in flower-pots, is allowed to expatiate unquestioned, and of course, we all gratefully acknowledge, often usefully upon the policy or impolicy of the various operations of the farm; but he who has witnessed and directed the operations of chemistry and life for years and over acres, who has long annually furnished the material and gathered the fruits of these operations over whole fields and farms, has his doubts or his convictions attributed to prejudice. It seems to me that if the word be properly applicable to whatever either of credulity or of dogmatism on any subject precedes experience, it can be least frequently applicable on agricultural subjects to the farmer. He at least comes to any agricultural discussion with experience to guide opinion; and he has, as I think, cleaner hands, on the score of sobriety and impartiality of judgment, than the enthusiast who charges him with prejudice because he does not believe that the profits of farming depend simply, to put it shortly, upon the atomic theory of the chemist. I at once confess that the analogy of agricultural experience, both of costs and of returns, leads me to prefer those plans for using London sewage by which it is applied to land in quantity, as in water meadows; and I have found that the experience of sewage farmers hitherto does generally sanction these plans. Still further, I may confess that, having investigated pretty fully both at Foulness, Dengie, and the Maplin sands, and through the line of country thither, the plans of Messrs. Napier and Hope for using London Sewage there, I believe them to be consistent both with ordinary agricultural experience and with that of sewage farmers generally. With this "prejudice" it was that I revisited the different places I have named; and now, finally dismissing these personal explanations, it is with this "prejudice" against me, I have to tell you what I saw and heard upon my tour.

1. First then of Rugby:—Here the washings of 8,000 people in a town which is, I understand, very fully supplied with waterclosets, are drained into a tank in the valley below, and thence continually, excepting nights and Sundays, forced by pump through several miles of underground pipe to one or other of various exits, some of them a mile away, on ground probably 60 or 70 feet above the level of the tank; and thence sometimes by hose, and elsewhere by mere surface runnels as in ordinary irrigation, the sewage is distributed, a plot or ridge at a time, over the grass land, until the whole surface of a field is overtaken. I am told £50 a year is paid to the town as rental for the manure—3s. or 4s. a day, or, including expenses of distribution and interest of capital, altogether probably some 30s. to 40s. a day for some 200,000 gallons; and I am told that none of those who rent it are satisfied with the result. Mr. Campbell, to whom a portion of the sewage is sublet, fails of a profitable result because he cannot get the sewage when he wants it, nor enough of it then. Mr. Walker, over whose land most of it is poured, is dissatisfied because of the injured quality of his pasture land, where it has been applied in large quantities. I have seen here heavy and early crops of Italian ryegrass, at least 10 tons per acre, in the month of April, grown on rather unkind land, chiefly by the aid of sewage; and we all know, from the published reports of the experiments superintended by Mr. Lawes, that the produce of the ordinary grass fields upon the lias clay land here has been wonderfully increased by the use of sewage, and nearly in direct proportion to the quantity applied. But it is worth noting that although the manure is here put upon the land at the cost of less than ½d. per ton, and not much more than 1s. per head per annum of the population who supply it, I did not meet with any one who was satisfied that it was agriculturally profitable. Let me mention here two other noteworthy things:—I saw coarse, couchy, weedy-looking stubble of grass, originally, I was told, good

grazing ground, which had been sewaged, and which after various mowings had latterly kept an enormous stock on it for some weeks to eat it down. This land had been lately valued for the purposes of ordinary agriculture as having been injured in selling value to the extent, I think, of £20 an acre, by being sewaged. And I saw good grazing land, which had been also sewaged, and was being sewaged when I walked over it—as full of clover and sweet short grass, and as abundantly producing first-class feed as any pasture I was ever over. Both had been sewaged—the one had been mown, and mown, and mown—and the other had been fed, and fed, and fed; the latter kept firm by the treading, and also no doubt replenished by the droppings of the cattle which lay thickly on the ground, had retained the original quality of the grass; which is generally, and at Rugby also as I have said, injured by the sewage irrigation where only mown crops are taken. As to the valuation of the land for ordinary agricultural purposes after a year or two of sewage, it is plain that any figures so obtained must be taken according to their strict meaning. The agricultural valuation of land must be made absolutely, and not for any special purpose, in order to learn whether any profit or loss has been sustained.

2. At Birmingham, the sewers which drain the two valleys over which the houses of 800,000 people are here distributed unite in tanks at the confluence of these valleys, for the settlement and deposit of their mud before the comparatively clear water is allowed to flow into the natural stream again. Some thirty acres of land have been here purchased by the corporation, and this mud is pumped by Walker's diaphragm pump to one and another section of this acreage, and as it dries it is dug out and carried away. This is creating such a nuisance, that at length they are pumping the sediment into barges on the canal within a few hundred yards of the tanks, and taking it to the various farms along the canal; in neither case however does the value received repay the costs connected with the process. In the meantime the soluble and valuable part of Birmingham sewage is going down the river as before. And as the water-closet system extends, both the nuisance of the tanks and the wastefulness of the overflow from them will increase.

The level lands near the tanks are occasionally flooded from the sewers as they were formerly from the river, and with about the same effect as formerly, according to the tenant, who denies the right of the corporation to charge a rent upon him for this water, which is, he alleges, no stronger than the original foul river water.

But it is flat land, and occasionally the water lying on the land has killed the grass instead of benefiting it. This is a contingency which may, I suppose, be occasionally looked for from the washings of a manufacturing town. It will be quoted by the advocates of scanty dressings as a risk to which those who use large quantities are especially liable. It appears to me to have been due to the flat surface, on which, with its imperfect surface drainage, the water must occasionally stagnate. Mr. Councillor Walker is urging the distribution of the overflow of the sewage tanks here, and declares that their 20,000,000 tons of it would, at even ½d. a ton, yield a monstrous revenue beyond the cost of distribution. It seems to me that here is an example of a central delivery of a great town drainage, where the water-closet system must be rapidly extending, which is ready for being turned immediately to agricultural account. It is however fair to mention, that several of the leading medical men in Birmingham recommend cutting off a portion of the supplies from the sewers immediately below the water-closets. Both Dr. Bell Fletcher and Mr. Cheshire, recommend contrivances by which much is retained, as in portable closed cesspools, for collection at monthly or half-yearly intervals by night carts as formerly. And this practice, if it should extend, would to some extent diminish the value of the waste.

3. We now come to the Edinburgh meadows. The

principal facts are that at Lochend and Craigenlinny on the north-east, at Grange upon the south, and Dalry upon the west, there are some 350 to 400 acres of grass land, over which the filthy natural drainage of the town is poured as in ordinary water meadows. The lands are generally a sloping, so as to enable a rapid flow, and the streams which wash out the valleys over which Edinburgh is spread, receiving the drainage of its houses, are of sufficient volume, when supplemented by the artificial water supply of the city which drains into them, to give an abundant irrigation to the land. From 10,000 to 20,000 tons per acre annually are thus distributed, in one or two floodings during every interval between the cuttings of the grass, of which three, four, and more rarely five, are taken in the course of the season. Perhaps the best illustration of the productiveness and value of the grass thus treated is furnished by the fact that there are about 2,000 cows in and around Edinburgh and Leith fed from these meadows during summer, or nearly six to every acre; and that between the middle of April and the end of October, they will on an average consume from 80 lbs. to 120 lbs. a day apiece, along with about half a bushel daily of spent malt from the distilleries. If the consumption of these cows be put down for 180 days at 100 lbs. apiece, the produce of the acre which keeps six of them must be close on 50 tons a year, and for this the average price paid is £23 to £25, or about 10s. a ton as it grows. I learned from a very intelligent man, who keeps 24 cows in Leith, that he has usually purchased at the spring auctions, when the year's growth is sold, 4 acres for his 24 cows, paying about £100 for them; and this perfectly tallies with the average result already given.

Some of the plots, they say (the grass is let or sold by auction for the year in acre and half-acre plots) are let or sold for as high as £40 the imperial acre, but the average price is £23 to £25 per acre. The worst pieces are the flattest and undrained, which are thus incapable of getting a rapid flow either over or through the land. The best pieces are those which face the south, which have a sufficient slope to permit a rapid flow of the sewage over the surface, and which are of so open a texture as to permit a good natural drainage through the land. It is worth noting too that while the inferior bits have by drainage been improved in productiveness, the best bits always remain the best; it is always particular spots, especially those which, owing to aspect, soil, and abundant supply of irrigation, are earliest ready for the scythe, that command the exceptional prices which are sometimes quoted by enthusiasts as if they were the average yield of the meadows. The early grass is worth to a milkman as much as 1s. per cwt. to go to the field and cut it for himself, although the average throughout the year is not worth much more than 6d., and that is how those early pieces fetch so long a price. It must also be understood that while grass—milk being 10d. a gallon in the Edinburgh trade—is worth 6d. a cwt. or more, perhaps, upon an average, to the cowkeeper to cut and carry a mile, or even two or three, yet it is not worth so much for any other purpose. It will answer for feeding neither cattle, sheep, nor horses; and thus it is that it is just in proportion to the demand there is for it for cows that the price is maintained or not. The prices named were as high twenty years ago as now. There were one-third fewer cows then than now, but there were just about one-third fewer acres then as well. As the demand increased and prices rose, more acres have been added. Italian rye-grass, broken up every third year and re-sown after taking a potato crop, has been grown at Lochend, and lying above the natural fall of the stream, it is watered by a self-acting pump driven by the stream itself; and fetches nearly the average price, although it does not reach the maximum achieved upon the best bits of natural grasses.

At Dalry, too, and the Grange, natural grasses, chiefly rye-grass, have been sown along with, in places, top-dressings of chopped couch, and watered by the foul stream, and equal productiveness has been soon acquired for newly

laid down pieces. Whatever grasses are sown originally, *Poa trivialis*, *Alopecurus geniculatus*, and *Glyceria fluitans*, with couch grass, crowfoot, and other weeds, and, where the land is best drained and dryest, rye-grass, catstail, cocksfoot, &c., ultimately form the pasture. And it would be pronounced by any one as I saw it last month, a wonderfully thick and luxuriant grassy surface, nothing like so coarse and weedy generally as the Rugby meadow, to which I have before referred.

At Craigenlinny, too, the meadows have been added to occasionally, and pumping engines have been erected to extend the limits of the area commanded by the stream; but they are no longer used, for it has been found here more than once that if but few acres in excess of the demand are brought into the market, the average price of the whole at once drops. I cannot too strongly impress upon promoters of schemes for utilising London sewage, that this is a very important part indeed of the Edinburgh experience for them to read—350 to 400 acres of this sewaged grass suffice for 2,000 cows. The people of Edinburgh and Leith are far better supplied with milk than those of London; but even there there is but one cow to every 100 of the population. And the 80,000 cows required at this rate by the metropolis would all be fed during summer, according to the Edinburgh rate, on 5,000 acres of grass. If there be any considerable increase in the supply of grass here beyond the Edinburgh rate, then it is plain from the Edinburgh experience that the Edinburgh prices will not be realised. Probably, the chief way out of this difficulty may be to copy Lochend in growing Italian rye-grass, for which there is a demand other than that of cow-keepers; but I cannot doubt that the marketing of the enormous grass produce which we shall obtain from London sewage will for many years be the greatest difficulty in the way of a profitable result.

Without discussing here, in detail, the quantity of sewage to which the Edinburgh results are owing, it may be said that the drainage of an area covered by more than 100,000 people is spread over 350 or 400 acres (we cannot, of course, infer from this that the waste from all these people reaches the land); that six to ten floodings are given during the growing season, besides, in the lowest lands, heavy floodings in the winter time—that the duration of the application varies from 4 to 40 hours at a time, and that the quantity applied varies from 10 to 20 thousand tons or more per acre in the year—that the grass produced is 45 to 50 tons per acre, capable of feeding 6 cows during the summer half-year; and that it is bought by men who are at all the expense of cutting it and carrying it home themselves for £23 to £25 per acre on an average, exceeding £35 and even £40 per acre in particular and exceptional plots. It may be also said that much of the land yielding nearly the average price is the poorest seaside sand; and that a great deal of it, watered with tail water which has already gone over land above, is just as good as the rest. It is all mowed and mowed, the produce being carried wholly away, and it maintains its productiveness year by year under this abundant sewage irrigation, notwithstanding this immense draught upon its resources. One fact more of great importance,—the poor, sandy land, notwithstanding the immense supplies of manure, is not enriched; a grain crop following the heaviest crop of grass, being unmanured, has failed; the potatoes following the Italian rye-grass at Lochend require to be most liberally manured. The Italian rye grass following last year's manured potatoes, sown in August and September, was looking splendidly last month at Lochend, and dressed as it will soon be with sewage, it will be worth, perhaps, £20 an acre during the coming summer. In 1866 it may be worth as much, but this growth and value is wholly owing to the supply month by month of the manure, not at all to the land, which is no richer at the end of all this manuring than it was at the beginning.

So much for the Edinburgh meadows. If the net gross proceeds of the land be put down as £8,000, there is

probably as much as 2s. a head obtained from so many of the population as contribute to the result, and diluted as it is (much of it, too, used twice), I do not suppose that more than $\frac{1}{4}$ d. per ton is obtained from the sewage. The Edinburgh results are obtained from the use of very dilute and already putrifying sewage in large quantities over slopes of light and well-drained land. And poor though they be as compared with the results and definitions of analysis, they are the most profitable results that have yet been anywhere obtained.

4. Compare them with those on farms near London.

(a) Near Croydon, Mr. Marriage deals with the sewage of 20,000 people, in a stream of 1,000,000 gallons daily, over an extent of about 250 acres. He uses the water a second or third time. His fields vary from 300 to 500 yards long. The feeders are 15 yards apart, and the "panes" or beds between them sink transversely at once from these parallel feeders across the breadth of them; and they sink, on the whole, in the length of them, about 1 in 400. There are no intervening drains, but any cubic inch of sewage may leave the feeder at the upper end, and, if not previously absorbed by the gravel subsoil, may trickle over the whole length of the bed to the transverse drain across it, 400 yards off; or it may leave the feeder 10 yards from the end, trickling only 10 or 15 yards to the drain close by. A very close and thick growth of grass, with clover appearing in the autumn, exists in the upper fields of natural pasture, which has come of itself after the Italian rye-grass without any direct sowing of seed, when the latter had died out, as it gradually does, after the second or third year. Italian rye-grass is sown in autumn, and keeps down two or three years, and is then broken up for mangel-wurzel and followed by potatoes, and then is sown down again. A cutting of 10 or 12 tons of grass in May is followed by others of about 7, 4, and 3 or 4 respectively, so that upwards of 20 and up to 25 tons of green food are got for sale. This, however, is certainly less than might be expected. Mr. Marriage declares that there is no good derived from drainage; mere surface feeding as it flows is depended on; but the gravel subsoil here does supply a natural drainage to a certain extent, and the ditches are deep enough to take advantage of it. Land in the neighbourhood, and this land before sewage, was worth £2 an acre; Mr. Marriage pays £5 and seemed in good spirits. He gets, I believe, upwards of 20s. a ton for grass in town 10 miles off, and 12s. to 14s. a ton for it on the ground, his own men mowing it and weighing it. Sewage helps the early growth amazingly. It is common to put it on twice between the cuttings, the intervals being five or six weeks, and the latter of the two dressings being often among the tall grass, when it is quite as efficient as elsewhere. It is put on for 30 hours at a time. The main facts are that the sewage all goes on filthy, and leaves the farm clean and limpid; and mixing up Mr. Marriage's plans for the future with his experience in the past, we may believe that it will leave behind it on the 250 acres available for it the following produce:—160 acres of Italian rye-grass at 20 tons = 3,000 tons at 12s. = £1,800; 60 acres of mangel wurzel at 20 tons = 1,000 tons at 20s. = £1,000; 50 acres of potatoes at 6 tons = 300 tons at 70s. = £1,050 = in all (under a rotation of three years, Italian rye-grass, mangel-wurzel, and potatoes) £3,850, or about £15 per acre. It is plain that this sum may be largely raised by an increase in the quantity of the Italian rye-grass; and this, I cannot doubt, must be obtainable. It is only gradually that a market has been obtained for the grass. At first there was considerable difficulty and some hay-making. Now there is a constant demand, but only an uneven supply. The second and third cuttings last year suffered from the drought, and under a hot summer sun it seemed that the tendency of the grass to throw up its seed-stem was unconquerable.

(b) At Cassiobury, the experience of the Earl of Essex, which is longer than that realised at Croydon, may be also named. There is here, from Watford, the sewage of

4,000 people, and 200 acres of land were provided with pipage to receive it; but I understand that his lordship has learned by experience of its comparatively small value in small quantities, to apply the whole of it over only 7 or 8 acres of Italian rye-grass during summer, cutting 30 or 40 tons per acre annually, and throwing it over 30 to 40 acres of his park land during winter.

(c) Mention must be made of the Camp Farm, Aldershot. 10,000 to 12,000 men use the latrines. These are flooded and flushed out at regular intervals, and the whole of the stuff is to come through 18-inch pipes of earthenware down to Mr. Blackburn's farm. This is 160 acres of poor gravelly, sandy, heathery waste. The subject here is only in estimate and anticipation as yet, although Mr. Blackburn has had experience elsewhere, by which he is guided both as to plans and expectations. Some of the stuff will flow over part of this land, and that part will always be available for the overflow of any remainder, which is undelivered by the pumping apparatus. Mr. Blackburn will pump by underground pipes to the centre of every five acres, and thence deliver through surface-pipes on wheels, to the centre of every $\frac{1}{4}$ acre, and thence by hose. A man will thus deliver, it is said, 400 tons a day, and 200 tons are expected to be a dressing for an acre. Drainage is obtained naturally through a gravel subsoil, and it is intended that none of the sewage shall flow off the surface; it shall all be used in the deepened soil, and it shall all be used on a minimum quantity of land in the first place, until that is got up to the right standard of fertility, and then the work will be extended. Italian rye-grass will be followed every third year by potatoes. Sixty tons per acre of the grass is the produce to be aimed at, and some 20 acres only are in the meantime being prepared. The plan here is to put the sewage on before it has time to rot, and to use it by hose and jet at the rate of 200 to 400 tons to a cutting. There is a quantity of water in land springs available, and useful for irrigation; but ordinary surface irrigation is not the plan advocated by Mr. Blackburn; he holds that only as a second resource. It is with pipe and hose, and with an economical use of the fresh material, that he declares to win.

It is plain that Mr. Blackburn's plans are directly opposed to those which have been productive of the Edinburgh result, which is due to irrigation in quantity with dilute and putrid sewage, and to a feeding not of the soil but of the plant.

These, then, are the facts, wholly agricultural—for I have not referred to the chemistry of the subject at all—on which the agricultural view of London sewage depends. The sewage of London differs from that of Rugby, Edinburgh, and Croydon in quantity alone. In every case there are from 40 to 60 tons of water to the annual waste of every individual of the population. In every case, as water-closets come more generally into operation, this filthy water will become more fertilising. Meanwhile, the actual agricultural experience elsewhere surely is the proper guide for estimate and foresight here. If we had 15,000 to 20,000 acres of light and sandy slopes below the present outfall of the sewers, this agricultural experience would point at once to a very easy solution of the problem. Failing these, Messrs. Napier and Hope propose to pump the whole of North London sewage (100,000,000 tons per annum) 50 or 60 feet, and let it flow along a culvert down to Foulness and the Maplin sands, where some thousands of acres, partly perhaps by purchase and partly by embankment from the sea, can be obtained, over which it may be poured, and there produce the 40 to 50 tons of grass per acre which are got at Craigentimny. This will be the almost immediate result; and thereafter year by year, on the farms along the course of the culvert, it is believed a demand for sewage will gradually arise to supplement the deficiencies of Essex agriculture. I suppose that in the immediate opportunity which is thus afforded of using all the sewage at the very outset, whether or not in an outrageously extravagant and wasteful way, as some people think (at all events very

much after the way in which Craigentinny is at present managed), combining with this the scope which is afforded for the gradual extension of a more economical and considerable use of the sewage all through the lower part of Essex, on its way to the final outfall, this scheme has the advantage of its rivals. It certainly has the sanction of the agricultural view of the subject which Rugby, Edinburgh, Croydon, and Cassiobury present; and while Aldershot, with its proposed economy of the material, is still a problem, yet, if that should succeed, it too may be copied easily and perfectly.

I propose now to devote the short remainder of this paper to a consideration of the scope which Essex agriculture, on the one hand along the line of the culvert, and the Maplin Sands on the other, at the termination of the culvert, offers for the use of London sewage.

The Maplin Sands, a considerable width of which it is proposed to embank, are a uniform slope of sheer and, not sufficiently inclined for catch-water irrigation, but sloped probably enough for the ridge line feeders of "lands" extending seawards at right angles from the shore; which lands might be laid out with sides sufficiently steep and with intervening drains also having fall enough; and several series of such lands, 300 or 400 yards long apiece, all pointing seawards, might be laid out in the breadth reclaimed; the cross main-drains of the first series collecting the water used there for a second use over the third series, and the tail water of the second series being used upon the fourth, and so on. The island of Foulness, on the side next the sand, all below high-water mark, is a comparatively light soil, and in places shallow, upon a sandy subsoil, quite suitable for irrigation, and capable of being laid out for it without much expense.

Excepting about Rochford and the Wakerings, and again over a tract near Stanford-le-Hope, where the soil is more or less free and light over gravel, the land all along South Essex, westward from Foulness, is a stiff clay soil. Most of it is arable—a proof of dry climate. Anywhere else than Essex such land would be in pasture, and if ever the rainfall be supplemented by even so small a quantity as 12 to 20 inches of sewage annually, it must be pasture here. Such stiff clay would be utterly unmanageable as plough land if frequently soaked either naturally or artificially. The drainage of the country is almost wholly a surface drainage: narrow ridges, the width of harrow, drill, &c., are worked by horses walking in the furrows, and these furrows are immediately cleaned out by a plough following the sowing machine, and they are then connected by cross-cut furrows cleaned out by hand where necessary. Steam cultivation has been adopted in places, and probably deep draining will succeed after it. It is wheat and bean land, with occasional vetches and fallow; straw is sold into London and dung brought back at about the cost of the straw. The whole country is London-clay and arable, growing corn and straw for sale, and buying dung. There is hardly any stock to be seen. And on Foulness the sales of straw to the bargemen and purchases of manure from the bargemen about balance each other in the year.

It seems to me that in the barren slope of worthless sand at one end of the line, in the immense scope which exists for an extension of the milk supply, of which I hope we shall hear something more this evening, at the other end of the line, and in the existence of an extensive tract of arable land without stock, whose straw is at present sent 20, 30, and 40 miles, manure being brought back as far, we have all the elements required for the profitable conversion of 100,000,000 tons per annum of North London sewage.

At the outset probably the demand for sewage along the line must not be counted on. But, then, these sands come into use. In the outset, too, we shall probably be over-stocked with the produce of the grass sown there; and hay-making may be required. Of course it is impossible to make 30 or 40 tons of grass per acre into

hay while the sun shines upon the land which grows so much. But I think it may be possible to make it artificially. Twenty-five tons of well-grown Italian rye-grass, which may make only £12 or £13 as green food, will yield probably 5 tons of hay, worth at least £20. In the manufacture of this quantity 20 tons of water must be driven off, and if this can be done for £6 or £7, there will be a profit on the process. The grass might pass downwards by zigzag travelling open bands or shakers, from the top of a shaft or building to which it had been lifted, and might during its passage downwards be subjected to a current of hot dry air upwards, so as to come out dry enough to stack; or it might be taken slowly along a long horizontal shaft, and subjected to the same influence, entering it green and emerging dry. There does not seem any difficulty on the face of it in thus dealing with that large surplus of green grass, which will certainly in the first instance be on hand. And if 6 or 7 tons of hay per acre are thus obtainable, the revenue should be even larger than if a direct sale were had for grass at 10s. a ton.

The books tell us that 6 to 10 grains of water would be taken up in every 100 cubic inches of space, raised from say 60° to 180° or 200°, even supposing it saturated at the lower temperature. To take up 20 tons of water in this way then, we should need a space equal to from two to three millions of cubic feet, and raise its temperature from 60° to 180° or 200°, and keep it (or, what is the same thing, keep so much air) at that temperature while it was passing through a shaft or passage for long enough to get saturated at the higher temperature from the moisture of the green grass as that was being brought along the passage. Can such a shaft or passage, say 4 feet deep and 10 feet wide, be kept at the temperature in question, and have air heated to that temperature driven along it at the rate of about 500 yards an hour for 24 hours, by the consumption of say five tons of coal? If it can, then hay can be artificially made at a profit. And although the sewage natural grass makes soft and worthless hay, that from Italian rye-grass is perfectly good. The conversion of the green grass into hay, is a change from goods for which there is insufficient market, and which will spoil if not immediately used, to goods for which there is always a demand, and which can be stored. And believing, as I do, that the immediate effect of any great extension, in the neighbourhood of London, of such an experience as that of Lochend or Craigentinny, or even that of Croydon (the only profitable examples by the way which we have to follow) would at once glut the market, and altogether overflow the demand for its produce, I feel certain that this question of artificial hay-making is of great importance.

Whatever the scheme adopted, there is no difficulty either on the score of engineering, or, where the abundant method of irrigation is adopted, on the score of the chemistry and composition of the material, to be anticipated. Neither is there any difficulty in the agricultural aspect of it, so far as the certainty of a crop is concerned; but I believe that during the first years of our agricultural experience of it, we shall be puzzled by a plethora of produce, for which there will be an insufficient market. It will be some time before the cow-keeping business will be transplanted from the grooves in which both food and trade have run so long, down to a new region, though it be of food so much more cheap and plentiful, and the question of artificial haymaking will have considerable importance during the period of change.

There is, however, another opportunity of a market afforded by the circumstances of South Essex agriculture.

Almost the whole of south-east Essex is arable, growing corn and straw for London, and fertilized by London dung, often at about the cost of the straw sold. There is, you may say, no stock. It is probable that if grass were supplied to the farmers here they would consume it in yards at home, and send milk or meat to London, making manure for themselves, rather than, at great labour and expense, send straw to London, and cart back the dung. And this, if it could be carried out, would be the best

way of disposing of the produce of the sewaged lands. The grass would be sold, if cheap enough, more easily than the sewage; and if it can be carried for 1d. or 2d. per ton per mile, I believe it can be delivered cheap enough to tempt a trade.

Green food properly consumed is worth 6s. to 9s. a ton to feed upon the land even in ordinary agriculture; near London, with a ready and immediate disposal of milk, it is worth from 15s. up to 20s. a ton. It is hardly possible to doubt either that cowhouses on a large scale, well situated near depôts of grass in a country where there is a great demand for dung, and an ample supply of straw, and where winter food may easily be grown—with ready access, too, to the London milk market, would at once be hired and worked; or that under such circumstances a considerable change in the style of agriculture of the district would gradually grow; more stock would be kept upon the farms, and the London milk trade would extend over the plough lands of South Essex.

Moreover, there is the opportunity offered to the tenants of all such lands as lie near the culvert, to use the sewage on their own lands and grow this grass themselves. I presume it is part of any and every plan of using the 2 or 80,000,000 tons per annum of London sewage to pump it into reservoirs on hill tops or rising ground wherever a local demand for its use occurs. Thence it may be delivered by hydrants or in runnels on the surface of the fields to be watered. I confess my strong preference of the latter to the former plan. There is all the difference between them that exists between labour-needing and self-acting machinery; and while it is of course thus distributed more cheaply, it may be also quite as economical in the use of the material. If I had only 10,000 tons of the stuff per annum to pour over 10 acres on a slope, (and this would, I presume, be thought a reasonable allowance even by those who advocate small dressings), I should prefer pouring it all over the highest acre, letting its tail water reach the others in succession by ordinary surface flow, to an equable distribution over the whole from equidistant hydrants, each of which must be managed by hand, delivering no more at a time than would sink into the land and there be all used. If, however, occasional reservoirs existed whence this sewage could be available in either way in different localities, we might safely leave those who have to make a profit by its use to their own devices as to its management. Anyhow, if by the use of surface irrigation great crops are obtained, and the water at a second or third use is perfectly clarified, then it is plain that the whole attainable result is arrived at; and great expense in hydrants and in detailed distribution will in that case be an expenditure for no useful end.

I believe I have only one additional remark to make, and that hinges on the conclusion here asserted—that if the water leave the land perfectly clarified, the whole attainable result is reached. This will be at once disputed, and is perhaps not absolutely true. In a dry season, no doubt, water, though free from fertilising matter, is itself invaluable, and in a drought it would often pay for pumping and for distribution; but when there is a question of gradually altering the whole style of agriculture of a county, I do not believe in this extra value of the mere water by which enthusiasts, in the advocacy of particular schemes, add on so many additional thousands of pounds to their anticipated receipts.

We have in this country varieties of rainfall amounting to 3,000 and 4,000 tons of water per acre per annum, but the value of the land depends very little upon this. The various styles of agriculture resulting from these differing circumstances do not, as a rule, differ materially in the quantity of rent which is possible under each. That depends on the composition and quality of the land; on the cheapness or abundance of manure, and on the neighbourhood of good markets.

On this subject, however, I must not longer detain you,

and I will conclude by naming the results to which this discussion of the subject has hitherto led.

Collecting these nearly into one, although I have not been able to overtake, within the allotted time, all the grounds on which an opinion must be formed, yet the conclusion to which I believe that the agriculturist is led after a study of the subject, is, that grass as the produce and ordinary irrigation as the method—both as involving a minimum of labour—are the proper agents by which the conversion, which we all desire, of London sewage into London milk will most profitably be obtained.

Certainly, on the clay lands of South Essex, to double or quadruple the present annual water supply by a sufficient application of this sewage would be altogether incompatible with anything but grass. On lighter lands with natural drainage, as perhaps ultimately on the Maplin Sands, it may be possible to use the liquid in the growth of mangel-wurzel or potatoes, and to take under able management one or other of these crops in triennial succession with Italian rye-grass, but elsewhere it must be grass, and only grass, that is capable of sewage treatment.

Another principal conclusion is, that the profitable conversion of the enormous addition to the grass growth of South Essex, which will follow the use of London sewage, can be expected only through a great and therefore necessarily a gradual extension of the London milk trade.

According to Mr. Lawes, we can depend on a ton of grass from every 200 tons or thereabouts of the sewage; and to this agrees the experience at Edinburgh. What if some 200,000,000 tons, taking both north and south London sewage, be annually converted by-and-by into grass, which, according to the Craigentinny rule, is good for hardly anything but cow food. We should every summer have a million tons of grass to eat—enough for 50,000 cows, in addition to the supplies already grown for the number by which London milk at present is provided.

Lastly, then, as a help out of this—one of the main difficulties which threaten the immediate profitability of any scheme for using London sewage—I hope that experiments may be instituted as to the possibility of artificial hay making.

It will have been observed that in the course of this paper I have made no reference to Mr. Moule's earth system of dealing with house waste, or to any other of the schemes of dealing with it in detail. The reason is, that I am constrained by the terms in which the subject is announced. The subject is London Sewage, and we are therefore shut up to a discussion of the question—how to use 200,000,000 or 300,000,000 tons of filthy water annually upon the land. That is the problem for consideration; and thus the discussion of methods fit for single houses, or for villages, is excluded.

Again, I have made no reference to the nuisance which may be expected from that agricultural use of this sewage that experience elsewhere seems to have recommended. I believe that the efficacy of the sewage as a manure will be dependent, to some extent, on its being already in a putrifying state; and no doubt a certain nuisance will be created. But if any alarmist here, ready charged with a denunciation of these plans on this account, be about to frighten us all with accounts either of putrid miasma and resultant fevers, or of new parasitic enemies, which through rotten sewage, rank and filthy grass, unhealthy cows and unwholesome milk, are thus to find their home in our bodies, breeding there disease and death, I hope that he and all of us will bear in mind that 400 acres of land, treated more wastefully and filthily than any of the London schemes propose, have been for a century and more under the very noses of the Edinburgh people; who have, moreover, been fed for generations on the milk of the cows which have consumed this sewaged grass. If any evils of the kind alleged are in the least to be expected, they must long ago have shown themselves in the death rate of so large a town; which, how-

ever, I believe, stands as low as that of any in the country. Lastly, it will, of course, be pointed out that I have named one only of the rival schemes for using London sewage. In choosing that one of the number for any particular application of those rules of practice and experience to which I have been calling your attention, I have followed the example of the shrewd and intelligent representatives of London who constitute the Metropolitan Board of Works. They, too, have followed the plans of Messrs. Napier and Hope, as being most worthy of adoption, and they cannot be supposed indifferent either to the general interest of Londoners or to the special interest of those among them who are ratepayers. It is plain, however, that in so far as the experience which has been described sanctions any other of the schemes which have been propounded, most of the remarks which I have made may be quoted by the advocates of those with equal effect.

DISCUSSION.

Mr. HENRY WEBBER said, through the kindness of Dr. Lankester, he was able to bring before the meeting some specimens of the sewage water of London, taken from the Barking outfall. Having been resident in Manchester for thirteen years previous to 1856, and his business (that of a cheese factor) having brought him into communication with farmers, he had seen the most astonishing results from the utilisation of sewage. He might mention one case in particular within his own knowledge, in which the area of grass land was barely sufficient for the maintenance of seventeen cows, the average yield of which was $2\frac{1}{2}$ cwt. of cheese per annum, and the same area of land was, by the application of sewage, made capable of supporting 47 cows, the average yield of which was $3\frac{1}{2}$ cwt. of cheese per annum each. This was sufficient, he thought, to show the great fertilising property of the sewage. Notwithstanding the great practical knowledge of Mr. Morton on this subject, there were some conclusions which that gentleman had drawn with which he (Mr. Webber) could not concur. The proposal to carry the sewage into Essex had been favourably spoken of in the paper, a county which, as the names of many of its towns implied, had only just freed itself from water. It was proposed to carry 100,000,000 gallons of sewage water annually to Ilford, Romford, Chelmsford, and through marshes where the division of land was not by hedges but by water, and by that means to bring that part of the country back again to the state from which it had only just been freed, and which had operated prejudicially upon the productiveness of the land, viz., excessive moisture. The question then arose, in which direction could they beneficially employ this sewage? To that he replied, they had only to cross the Thames and go into the county of Surrey, where they would find a dry parched soil, much better suited for the application of the sewage, which would convert that which was now almost an arid sand into good fertile soil. He had travelled hundreds of miles over the plains of America, and he had not seen anything so sterile there as was to be met with in the neighbourhood of Woking and the Frimley ranges. He believed to take the sewage into Essex would be a failure, and the result of that failure would be to set aside, for centuries, perhaps, any further attempts to give an agricultural value to this product. It should rather be taken where the soil needed it—to the dry and sterile soil of Surrey, where they might look for the very best results from such an application.

Mr. WALKER (of Rugby) said that the extensive pollution of an otherwise beautiful stream in the locality in which he resided induced him, 12 or 13 years ago, to turn his attention to the question of how best to apply the sewage of towns to the land, and from that time to the present he had been more or less occupied in the endeavour to solve this problem, and he had great pleasure in stating that he believed he had at length succeeded in doing so. He had heard all sorts of enthusiasts crying sewage up and others crying

it down, both going equally far from the truth, till at length the happy medium, he believed, had been arrived at. But there were some points on which he thought there was still a slight diversity of opinion. Mr. Morton had told them that almost the only way of applying the sewage was by the creation of water meadows. He (Mr. Walker) thought it was probably the best way, but it was by no means the only profitable application of it. In many cases this was undesirable. The object of his experiments at Rugby had been to endeavour to utilise the sewage mainly on pasture land, and, in some measure, upon cereal crops; and he considered what had been done at that place was sufficient to show that sewage could be applied very profitably on good pasture land, without deterioration either to the crops or to the land, and also without producing a nuisance. He thought Mr. Morton had in some measure answered his own arguments on that point, for he had pointed out how difficult it was with the produce of water meadows—only suitable for feeding cows—to obtain a market for the grass if cut, and that was in itself a serious difficulty. For instance, at Rugby, if all the sewage were turned upon the water meadows, the town could not consume the produce of the cows required to feed off the grass, though if it could be artificially converted into hay by the ingenious plan suggested by Mr. Morton, that might remove the difficulty; but at present, however, in small towns it was insuperable under existing arrangements. Therefore, it was of importance to have experiments to show that sewage might be profitably employed on flat pastures, and that he conceived had already been shown at Rugby. Mr. Morton had stated that some of the land there had been completely spoiled. That was quite correct. Land more shamefully spoiled he had never seen than that under the operations of the Royal Sewage Commission. Mr. Morton also mentioned that he had seen other land in the same neighbourhood sewaged and fed off, which was most excellent turf, full of fine grass. That land had to his (Mr. Walker's) knowledge been fed for the last twelve years. There was very little land in fact that had been more continuously watered, but it was not spoiled, because the crop was kept down by feeding; and he maintained, whether it was kept down by the scythe or by the mouths of animals was immaterial; it must, however, be kept down. Directly grass which was watered was allowed to run wild it became coarse, and when the fine grass was destroyed it could not be restored without re-sowing. The great point, then, was, whatever quality of sewage they put upon the land, to take care that the herbage did not run away. It was precisely the same with the trees in a shrubbery. If there were means of stimulating the growth of the trees five-fold, and they were neglected for four or five years, the plantation would become a tangled jungle. So it was with these pastures; and that was the history of the great part of the failure at Rugby. It was obvious that in many towns there were great objections to creating water meadows, which sometimes became, more or less, a nuisance in the neighbourhood; and, therefore, it was, if the system of improving the pastures by moderate watering would be efficacious, that would, in most cases, be the best means of utilising the sewage. The quantity used years ago, however, was far too small to do good. At one time they talked of 5,000 gallons per acre. That was the quantity recommended in the first report of the Board of Health; now they heard of 6,000, 8,000, and 10,000 tons per acre. His impression was, as far as he had seen, that if they mowed or fed the crops carefully they might produce enormous crops with 750 tons per acre spread over five dressings during the year. Supposing, however, they wanted simply to make the most of a given quantity of sewage, if the mode of applying it was necessarily expensive, then they might limit the area and increase the quantity per acre, and, within certain limits, *vice versa*. Rugby had been constantly mentioned as an instance of failure, and more so lately from the grievous failure in one sense of the ex-

periments of the Royal Commissioners. Four years ago two of his own fields were arranged in plots for experiment; these plots were severally watered in different degrees, one plot not being watered at all. That portion which they watered extravagantly, drowning it at one time and allowing it to become parched up at another, produced very largely at first, but afterwards the grass became very poor. The next plot, which was only less drowned, was slightly less productive, because the parching process had greater prominence; while a third plot, more parched than drowned, produced still less. Such a mode of application was the cause of the want of success of the experiments of the Commission. It was mentioned in the paper that Mr. Campbell, who rented some land of his, had applied a portion of sewage to that land; but the fact was, that gentleman's land all lay so high that he could get only a small proportion of sewage, as the surrounding country was at a lower level. The arrangement for supplying Mr. Campbell was made at the time when it was supposed that a very small quantity of sewage was sufficient; but now it was shown not to be so. He had two other tenants of land who had also declared themselves dissatisfied with the results of sewage irrigation, but in their cases he did not hesitate to say that the failures were occasioned solely by mismanagement. Moreover, when this plan was first commenced, only the sewage proper was allowed to go down the drains of the town; but the pipes were so laid that they very soon became choked, and the surface water of the district was employed to flush the sewers out. The consequence was, in dry weather, these surface drains had no effect. Last summer there was not water enough to keep the pumps at work, and in heavy rains they were drowned out; and with but a small amount of rain there was so great a dilution that the effect of the sewage was very greatly deteriorated. Still he was not less confident than he had ever been that the sewage of towns might be profitably employed to irrigate flat meadows, and he believed also to enrich land for cereal crops. If it was to be done at all, it should be by saturating the ground time after time, allowing it to dry to a reasonable extent before the growing crop was upon it. He would make one other remark with regard to the outfall for London sewage. He thought it to be regretted that the money which was being spent in collecting the sewage at Erith was not spent in erecting a system of steam engines and pipes for collecting it at different points, and making it radiate in various directions—north, east, south, and west; but, as this error had been committed, he thought the scheme for utilising the sewage in Essex was the best thing that could be done with it.

The CHAIRMAN asked, supposing Mr. Walker had to begin the system at Rugby again, what area would he consider sufficient for utilising the sewage of that town?

Mr. WALKER replied he should be disposed to lay pipes nearly to the same extent as he had done already, but they would not be strictly necessary. He could utilise the sewage over a much smaller area, and if the object were to get rid of the sewage, one-tenth of the present area would be quite sufficient for the purpose.

LORD ROBERT MONTAGU, M.P., begged to bear his testimony to the merits of Mr. Morton's paper. He trusted he should not be deemed guilty of presumption in venturing to state a few points on which he differed even from so high an authority on these matters as Mr. Morton. That gentleman, in an early part of his paper, made use of this expression—"I at once confess that the analogy of agricultural experience, both of costs and of returns, leads me to prefer those plans for using London sewage by which it is applied to land in quantity." Now he (Lord R. Montagu) was at a loss to know what those analogies in agricultural experience might be. When they put farm-yard manure upon the land, did they put it on in unlimited quantities? Did they not put it on rather sparingly? Did not the farmer carefully calculate how much manure the extra crops produced would pay for?

and no more than than would be put on his land. In like manner, if he used guano, he would carefully regulate the quantity. The rule laid down by Professor Way was that they should only put as much manure on the land as it would readily absorb. The power of land to absorb was extremely limited. If they put more sewage on the land than it could absorb it ran through the land, did not enrich it, but, on the contrary, injured it, and the sewage that ran off entered the streams in the neighbourhood, and the health of the population was thereby endangered. But what was the reason Mr. Lawes gave for putting these large quantities of sewage on the land? He merely did so, he said, to get rid of it—not to get larger crops. The speaker having quoted from Mr. Lawes's evidence on this point, went on to observe that the only reason Mr. Lawes gave for putting this unlimited amount of sewage on the land, was to get rid of the sewage. At Croydon, when they commenced utilising the sewage they began with a small area. They found it occasionally a nuisance; the mud deposited on the land became putrid. They enlarged the area from 56 acres to 100 acres, still it was too small; and they then enlarged it to 260 acres, to which they were restricted by an unfortunate contract they entered into; but they would have been glad to have increased the acreage. Mr. Morton seemed to have been somewhat aware of the mistake he had made in the earlier part of the paper; for he said that Mr. Blackburn, who was the person who employed the sewage at Aldershot, applied only between 200 and 400 tons per acre per annum. If that were good, what must they think of a gentleman who, in his evidence before the Parliamentary Committee, said he would put on 50,000, 60,000, and even 70,000 tons per acre. That would be equal to a rainfall of the depth of the room in which they were assembled.

The CHAIRMAN remarked that he believed Mr. Blackburn's work had been only recently commenced—three months ago—so that there must be some mistake as to any annual amount he had been said to have applied to the land.

LORD R. MONTAGU—From Mr. Blackburn Mr. Morton passed on to Mr. Walker (of Rugby), who gave excellent evidence before the Committee. It was said that Mr. Walker was dissatisfied because of the injured quality of his land, the alleged deterioration being to the extent of £20 per acre. That truly was the evidence of Mr. Walker with regard to that part of the land over which Mr. Lawes applied the sewage; but a part of the land had remained in his own hands, and that did not pay him; but if he rightly understood the evidence of that gentleman as well as that of others, it was because he had patriotically gone to a large expense in erecting engines and laying down pipes, and by that means diminished his profits. He now came to that portion of the land over which Mr. Lawes had applied the sewage, which was three acres in extent. Mr. Morton said not only was it wrong from the quantity of sewage put on it, but also from the precise rules which were laid down by Mr. Lawes himself, viz., that at such and such times the sewage was to be applied, and at certain precise periods the grass was to be cut. The grass grew long and rank, and rotted at the roots, but Mr. Lawes did not cut it because the prescribed time had not arrived. At last the haymaking time came, and the grass was cut and carted away, while the rotted roots were left to bake in the hot summer sun, the land was parched and cracked, and all the grass worth having was killed. Mr. Morton was perfectly right in saying that he only saw coarse, couchy, weedy stubble of grass. What else could be expected on land at one time drenched with moisture and at another time baked by the heat. Mr. Napier and Mr. Hope stated in their evidence that the Rugby experiment was no criterion at all; and they trusted at least that their own experiment, if ever it was carried out, would be more successful than that of Mr. Lawes. He hoped the same

thing. In another passage of his paper Mr. Morton stated that Mr. Lawes's experiments showed that the crops were increased in direct proportion to the quantity of sewage applied to the land. He would again call to their mind the rule of Professor Way—that they could only successfully apply so much sewage as the earth could absorb, and that which ran away from the land was sheer waste. Professor Way stated further, that the colouring matter in the sewage was due to certain fertilising elements in suspension in it; but so many of these were soluble, that if water apparently pure ran off the land it was no proof that none of them were carried away along with it. If it passed away in a coloured state, *a fortiori*, one of the fertilising elements were carried away. With regard to Rugby, Mr. Lawes stated that the sewage which ran away through the drains was highly coloured. That proved that he put on so much that a great deal of it never reached the roots of the crops at all? The results of the experiment of increasing the quantity of sewage were these:—On the unsewaged land the crop of grass was nine tons per acre; with 3,000 tons of sewage the produce was twenty-two tons; with double that amount of sewage the produce was only one-third more; with 9,000 tons of sewage only one-fifteenth more; which showed that the crop was not increased in proportion to the quantity of sewage applied. It might naturally be asked what was the result with a smaller quantity than 3,000 tons, but this experiment Mr. Lawes had not tried. But there were other witnesses before the committee, such as Mr. Meehi, who used only a small quantity of sewage. Mr. Walker had stated this evening he would not apply, on an average, more than 750 tons per acre; nevertheless Mr. Lawes asserted that he would go even to the extent of 70,000 tons an acre. Mr. Morton had stated that he had not met with any one who was satisfied that the application of sewage to the land was agriculturally profitable. He imagined that the essence of the paper applied to Rugby alone; but he thought they had altogether disposed of Rugby, inasmuch as Mr. Walker stated that the experiments there proved nothing. Mr. Morton had alluded to Edinburgh, but there were a few matters he had left out. The application of the sewage at Edinburgh was described by Mr. Rawlinson, and Professor Way, and he believed by Mr. Hope also, as clumsy and bad, and the waste of manure was enormous. But what were the agricultural advantages even under that acknowledged imperfect method? In the autumn of last year he visited the Craigminty meadows. The sixth crop had then been cut, and the seventh was on the field knee deep. He was told that formerly that land had let at 2s. 6d. per acre, and was now bringing £40 per acre. Coming back again to Croydon, the sewage of a population of 17,000, amounting to nearly a million gallons per day, used to flow into the Wandle. Numerous actions were brought against the Local Board for the damage thereby done to the stream; amongst other complaints was that of the fish in it being destroyed. No fewer than seven actions and injunctions were tried, at a cost to the Croydon Board of some £10,000. Vice-Chancellor Wood, on the authority of various scientific witnesses, declared that it was necessary to apply the sewage to the land before it should be allowed to flow into the river. Upon this the Board tried the methods of precipitation and decolorising, which had been unsuccessfully adopted at Leicester and Tottenham. Mr. Rawlinson stated that between the law suits and these attempts at disinfection, the Board expended no less than £24,000; while, he added, the whole of the works for irrigation might have been completed for £20,000. As soon as the sewage was applied to the land the price went up to £4 per acre, and the Board sub-let it to Mr. Marriage for £5 per acre. From the evidence of the Chairman of the Croydon Board, it appeared that Mr. Marriage realised a crop of grass on the 260 acres which produced him £32

per acre. He asked were not these instances sufficient to prove the profitable results of the application of sewage to the land? Mr. Morton had alluded to the case of Birmingham, and stated that the sewage was brought into tanks before the supernatant liquid flowed into the river. The soluble parts in this fluid, however, contained six-sevenths of the whole value of the sewage, and this, as stated, was carried away by the river. Mr. Morton had said that the soil was not permanently enriched by sewage, whilst a contrary opinion was entertained by Professor Way.

Mr. Morton explained that that expression referred only to the sandy slopes of Craigminty.

Lord R. MONTAGU—One other subject was referred to by Mr. Morton, who stated that the rainfall throughout England was equal to an average of 3,000 to 4,000 tons of water per acre, but that the value of the soil depended very little upon that, but very much on the nature of the soil. The water percolated through light soil till it came to a bed of clay, and it ultimately made its appearance in the valley as a spring; but if it fell on clay soil it remained there till it was either evaporated by the atmosphere or percolated very slowly through the soil. In Huntingdonshire, which was his own district, the farmers complained that the land was overdrained; the water percolated quickly through the gravelly soil and the ground became parched. In the clay land districts the demand was for more deep draining. It was clear from this that sewage when applied to gravelly soils would enrich them; but if it were applied to undrained clay land it only made the evil worse. They already held the rain water, and unless the land were drained, it would only be made cold by the application of sewage water; therefore, the two subjects of the application of sewage and the drainage of heavy lands were intimately connected together. He would conclude by congratulating Mr. Morton upon his able and lucid paper, and by felicitating him also upon his fears that this country would soon be embarrassed by a plethora of grass produce and by the consequent enormous amount of milk which would be produced. He thought the inhabitants of London could very well put up with a large supply of pure milk from Essex and other parts of the country.

The CHAIRMAN observed that there were evidently a considerable number of gentlemen present who were desirous to speak on this highly interesting and important subject, and, therefore, if it was agreeable to the meeting, he would suggest that the discussion be adjourned.

The discussion of this subject will be resumed on Wednesday evening next, the 8th February, at 8 o'clock.

Mr. THOS. WALKER, of Birmingham, writes as follows:—

Many persons have the idea that the silt, or mud, and other suspended matters (of which there is but one ton in 1,170 tons of sewage) are alone valuable, and that the water is worthless. This is a great mistake. The most valuable manurial matters of the sewage are those held in solution by the water; the dirt being of small comparative value. The fecal, urinal, vegetable, and animal matters passed into the sewers from water-closets, urinals, slaughterhouses, stables, markets, &c., are, in their passage from the sewers to the outlet, completely deprived of all their soluble portions, by the large volume of water always accompanying them. Let it therefore be well understood that the value of the sewage is in the water alone after the dirt has been taken out of it; as, however much clarified it may be, it will still hold in solution—as sea-water does its salt—all the soluble elements of the decomposed animal and vegetable matters; and only then is it in a fit condition to be used on grass land, as it would otherwise cover the grass with an injurious and offensive deposit and scum, which would close up the pores of the leaves and prevent their taking up atmospheric food. It is then also free from smell; the putrid and undecomposed matters having been all taken out; and, moreover, the solubles, being dissolved in and

incorporated with so much water, will keep sweet and clean for any length of time in the reservoir; besides which, the presence of the dirt would be liable to injure the large pumps, and to lodge in and choke up the carriers. The mud can be taken out, and, by itself, removed to any distance, there to be used as manure for other than grass land. For separating the solid from the fluid matters, years of experience have proved the filtering system to be impracticable, and that a simple settling pit is sufficient, provided that it be made large enough. The method I recommend is as follows:—I pass the sewage, direct from the sewers, into a trough of a certain form, and of a size proportionate to the flow and quality of the sewage; in this trough only the stones, grit, and other heavy matters subside, and from this trough the sewage passes, with its more fibrous suspended matters (through a grating that intercepts rags, paper, &c.), into a large settling pit, capable of containing several hours' flow, and of a convenient construction for facilitating the settling and subsequent emptying of the mud. (It is better to have two of these settling pits, so that the sewage may be depositing its mud in one while the other is being emptied.) In this latter pit the remaining non-decomposed matters are deposited by subsidence, the water passing off clear at its far end to pumping-engines. The pumping-engines, working night and day, will pump the clarified sewage through an underground cast-iron rising main to a large reservoir, capable of holding several days' flow, on any suitable high elevation, from which rising main and the reservoir, any land below can be irrigated by means of branch carriers, which will also be laid below the surface. The distance from the pumps to the reservoir may be several miles. To every 220 yards of the rising main there will be branches, right and left, to which will be attached long carriers, with 6-inch hydrants or taps at every 220 yards. There may be also large service-pipes, starting from the reservoir, in different directions, to be taken through other land where the sewage may be required, in the same manner as described in reference to the rising main and its carriers. As 220 yards square is equal to ten acres, there will, therefore, be a 6-inch hydrant to every ten acres, from which the farmers will (by trenches or otherwise) take their supplies. The farmers situated in any part of the district over which this net-work of carriers extends, will thus be able to have the sewage at any time and anywhere they may require it. The quantity used by each consumer can be ascertained by a water-meter attached to each hydrant, or so much an hour may be charged for each hour that each hydrant is open. The silt or mud is pumped by a diaphragm force-pump from the large pit, through an iron carrier, to any convenient destination. It will be better to have a small separate engine to work the mud-pump, as it will only have to be in action a few days in each month, when the mud is required to be removed; whereas, the Cornish pumping engines, by which the clarified sewage is elevated, will have to be worked night and day. Before concluding, I will make a few remarks on the subject of the Birmingham sewage. The Birmingham Corporation have spent many thousands of pounds in constructing filtering beds and tanks for the detention of the solid or suspended matters of the sewage, not with any view to its utilization, but for the sole purpose of keeping the mud out of the river Tame, as they are under an injunction forbidding them to pass it into that river, into which, however, the valuable clarified sewage is still allowed to flow. The corporation have laid down works for the removal of the mud deposited in the subsiding tanks direct to boats, on a canal about 500 yards away from the tanks, by forcing it through a carrier rising some yards on its way to the boats, by means of the diaphragm pump before referred to, and are sending it to farmers on the banks of the canal for use on their land. Birmingham, from its population of 300,000 inhabitants, produces 12,000,000 gallons of

sewage daily, being 40 gallons per head per day, or 20,000,000 tons per annum, which would give 4,000 tons each for 5,000 acres, or 1,000 tons each for 20,000 acres. We find, by the levels of the district, that we should be able to have a summit reservoir not more than 100 feet above the mouth of the sewer below which there is plenty of adjacent land to consume the whole of the sewage, even if it were used over 20,000 acres, the owners of which land would doubtless be willing to pay such a price for it as would amply repay the company supplying it, even if the sewage were sold at very much below its real value. The average value of the fertilising elements held in solution by each ton of town sewage, has been variously estimated by chemists, at from 2d. up to 3jd., taking the price of guano as the standard. This 2d. to 3jd. is without taking into account the irrigating value of the water itself, which latter consideration accounts for the farmers who have used it in light dressings having found it to be worth from 5jd. to 9d. per ton. Now, as 4,000 tons per acre per annum have, in some cases, been applied—although it would be more economical and productive to use it over a larger area, and the cost of plant would be less in proportion—we will take that as our basis to get at an estimate of the cost of works required.

ESTIMATED COST OF RAISING SEWAGE.

The average duty of Cornish engines is 56,000,000 lbs. raised one foot high, with one bushel, or 94 lbs., of Welsh coal, the cost of which would be, say 5d., reckoning the coal at 10s. per ton.

As 56,000,000 lbs. are equal to 25,000 tons, we have:—

25,000 tons raised 1 foot for 5d. cost of fuel	
or 250	100
" 100	" 5
" 100	" 2

The cost of fuel for raising 100 tons 100 feet high would therefore be 2d., which gives £4 11s. 4d. as the daily expense in fuel. If to this be added 2d. per 100 tons for wages, grease, and other incidental expenses, the daily amount of which would likewise be £4 11s. 4d., and is evidently sufficient, the total outlay would be £9 2s. 8d. per day, or £3,333 13s. 4d. per annum, for raising the whole of the Birmingham sewage to the above-mentioned reservoir. Any water-works engineer will verify this statement. The cost would therefore be 4d. for 100 tons, including fuel, wages, and all other working expenses. This gives twenty-five tons for 1d. I have carefully considered the cost of constructing the necessary works for the utilisation of the Birmingham sewage over 5,000 acres of land, and am of opinion that, inclusive of purchase of land, parliamentary expenses, 62½ miles of iron pipes, 500 hydrants (being one to each ten acres), the summit reservoir, Cornish engines, pumps, and other apparatus, the total capital required would not exceed £140,000.

ESTIMATED VALUE OF SEWAGE PER ANNUM.

20,000,000 tons, even at ½d. per ton,
will amount to.....£41,666 13 4

This ½d. per ton is not near the value of the fertilising elements held in solution, exclusive of the irrigating value of the water itself; but I have put the sewage down at ½d., to show that at that low price it would still pay good dividends, even if only two-thirds of it were paid for.

Annual working expenses, including fuel, wages, &c., for raising the whole 20,000,000 of tons to the reservoir, 100 feet high £3,333 13 4

ANNUAL INCOME AND EXPENDITURE.

Proceedings of Institutions.

THE METROPOLITAN DISTRICT.—Mr. H. H. Sales, Visiting Officer of the Society of Arts for the Metropolitan District, writes as follows:—"Since the commencement of the winter season, the work of the Society of Arts, with reference to education, has made great progress in this district. Previously, but few classes, apart from Institutions, had been established for advanced subjects. The standard of attainments in the ordinary night schools was too low to meet the requirements of the Examiners or the Society, even in those schools that attempted to give instruction in other subjects than reading, writing, and arithmetic. In September, classes, on the same plan as that adopted in the City of London College and London Mechanics' Institution, were opened in St. Michael's School-room, Bromley, by Mr. Edmund Hay Currie. The fees paid by the pupils render the classes self-supporting—a most important element as regards their success—and at the same time are sufficient to engage the services of most efficient teachers. The classes of the West London Youths' Institute have been remodelled on a similar plan. In Bethnal-green, self-supporting classes have been established in Abbey-street Schools, and likewise in St. James's Schools, Ratcliffe. A Board of Education for the parish of Islington is in the course of formation, and the organization of classes will form an important part of its operations. The displacement of the common night school by efficiently-conducted, self-supporting special classes, is a marked feature in connection with the progress of adult education in the metropolis. It must not be supposed that the rudiments of education are neglected under this class system. In all these classes an elementary class is included for instruction in reading, writing, and arithmetic, and is generally conducted by a certificated school-master. The Society's system of examinations, certificates, and prizes, gives a collegiate form to the classes, and exerts a great influence upon the students. I regret to say that I cannot bear like testimony to the present scheme of Elementary Examinations conducted by the District Unions. A working man who wishes to study some particular subject, while recognising the wisdom of the Society's regulation respecting a preliminary examination in reading, writing, and arithmetic, cannot see the use of being likewise compelled to study geography and English history; and, consequently in my district the great majority of the candidates who will present themselves in the ensuing Final Examinations will obtain a "pass" from a Local Board, and not a "certificate" from the District Union. Although this action will not affect the Society's Final Examinations, yet it will seriously influence the Elementary Examinations held in connection with it by the Metropolitan District Union. I am strongly of opinion that the Lower Grade Examination should be confined to reading, writing, arithmetic, and dictation; and certificates should be awarded in the Higher Grade for greater proficiency in the same subjects together with elementary grammar and composition, and that geography, English history, and Gospel history should be excluded from the Lower Grade, and not be indispensable for a certificate in the Higher Grade. If the Lower Grade Examination was a stepping stone, as it were, from the day school to the evening class, and the Higher Grade certificate a standard of proficiency in elementary knowledge, I submit that the Elementary Examinations held by the District Unions would then assist in carrying on the education of the day school, and in preparing duly qualified candidates in elementary knowledge for the Final Examinations."

OPERATIVE COACHMAKERS' INDUSTRIAL EXHIBITION.

On Wednesday, the 1st of February, the public open-

ing of the Operative Coachmakers' Industrial Exhibition, in the Coachmakers' Hall, Noble-street, took place in the presence of a large number of persons, the Marquis of Lansdowne presiding at the ceremony. The very reverend Dean Milman was also present, and several members of the Coachmakers' Company.

Mr. G. N. HOOPER, of the Haymarket, read an address on behalf of the committee of management, from which the following is extracted:—

"On the occasion of publicly opening the first Industrial Exhibition of the Operative Coachmakers of London, in this corporate hall, every one must feel that a striking contrast is presented between the present state of the coachmaking trade, and the position it occupied when the Company of Coach and Coach-harness Makers received its charter from the hands of King Charles II., May 31st, 1669. At that period trades were mysteries and their processes secret. The present exhibition, however, illustrates a vast change, not only in the processes employed, but in the altered state of feeling on the part of employers and workmen, who now court inquiry, comparison, and inspection of their work, hoping to interest the public by showing how much ingenuity, patience, and care are necessary for the production of a first-rate carriage. Carriages of a rude and uneasy description were invented at a very early date, and were in use among the Israelites, Egyptians, and Assyrians, as recorded in the sacred writings and upon their sculptured monuments. The Greeks and Romans made very little improvement upon the Egyptian carriages, beyond inventing four-wheeled vehicles, and the art seems to have slumbered for many centuries. It revived at length and attained great excellence in Italy in the fifteenth and sixteenth centuries, and became spread over other countries. In the time of Queen Mary, 1556, we find mention made of a coach suspended on leather braces; this may have been sent to her from Italy, by her relations who then ruled over that country. This was the commencement of the improvement in the art of coach building in England, and this art was soon so extensively patronised that the writers of the times foretold that the use of carriages would enervate and enfeeble the people, who ought to be satisfied to travel on horseback as their forefathers had done. We may congratulate ourselves, however, that although carriages are now in daily use by all classes of society, we see no signs of that enervation which our ancestors predicted. Since the introduction of railways, the number of carriages has multiplied to an extraordinary extent, assisted by the reduction of the tax upon them, by Mr. Gladstone, in 1853. This increase, has moreover, stimulated industry and invention. The sound and honest character of English carriages has long been appreciated throughout Europe and every country in the world, and for many years has secured a preference for the English trade. Our carriages have, for upwards of half a century, been considered the best in the world, both in design and durability. The idea of rewarding working men for great skill, as well as master manufacturers, is not new; like many other seeds, destined to bear good fruit, this idea arose during the organising of the Great Exhibition of 1851. It is a matter of regret that we have not been able to promise protection and full security for inventors of new and useful improvements. The patent law, as it at present exists, is both an evil and a good, the dread of exhibiting before the invention is secured often prevents the very exhibition in which hints for perfection might be gathered on one hand, and beneficial sale for the improvement be secured on the other by this sort of publicity. These exhibitions specially offer encouragement for young journeymen to make known their own original ideas by drawings and models; they can thus gain opportunities for advancement and becoming known. Had the committee been able to make the proposed exhibition more generally known, and to have given longer time to prepare objects for exhibition, a much larger number of exhibitors and interesting drawings and models

would probably have been the result; but the near approach to the London season, during which the time and strength of both master and man are taxed to the utmost, forbade any lengthening of the time of preparation, and to defer the exhibition to the autumn might have been to cool down the cordial and expectant feeling that had been raised. It was thought better that a small collection of objects sufficient to fill the hall, containing in itself examples of modern progress, with relics of the past and memorials of true excellence in the art, the whole enshrined in its fitting place of exhibition, the hall of the Company of Coach and Coach-harness Makers, would be better than attempting a more ambitious exhibition."

After an address from the CHAIRMAN,

The Old Hundredth Psalm was sung. The Dean of St. Paul's having offered up a prayer, the Anthem, "Thine, O Lord, is the greatness," was chanted by amateurs, who were coach operatives; and, after "God save the Queen," the Chairman declared the exhibition to be open.

SOUTH LONDON INDUSTRIAL EXHIBITION.

This Exhibition was inaugurated by the Bishop of Winchester, on Wednesday last, at the Lambeth Baths, in presence of a moderately large assemblage. The guarantee fund for the present exhibition is £1,108 5s. 6d., an ample sum for the purpose, and a large number of the guarantors are working men. The prize of £5 for a design for a commemorative medal has been awarded Mr. R. W. Martin, a working man of Walworth. A gallery runs round the walls of the building, and on the front are hung panels recording the various places in the south metropolitan districts from which articles have been collected. There are numerous models of villages and of ships, drawings, paintings in water-colours and in oil, as well as plaster busts and models in terra cotta. The whole exhibition numbers 640 articles of various kinds. The Bishop of Winchester delivered an address, and some hymns were sung.

Fine Arts.

ESTIMATION OF WORKS OF ART.—The tide seems to run just now more strongly in Paris in favour of the work of French artists than of those of the great masters of Italy and Flanders. Not that any work of any French artist will fetch, even in the Paris market, as much money as a Raphael, a Michael Angelo, a Rubens, or a Murillo, but the relative value of the former is certainly on the rise. At a sale of the works of the sculptor Cordier, a living artist, 58 items realised 59,000 francs (£2,360). The statue of an Arab woman, in onyx and bronze, was purchased by the Duc de Morny for 6,825 francs; a marble statue, called "La Belle Gallinara," seen in London in 1862, if we remember rightly, was sold for 4,100 francs; and two other statues for 3,800 and 3,000 francs respectively.

SALE OF A VENETIAN GLASS.—A most extraordinary instance of growth in the value of an article was exhibited the other day at the sale of the collection of M. Alfred de Knyff, at Brussels. A glass, of Venetian manufacture, which had been purchased but a short time since for one franc, was purchased by a dealer for 1,000 francs.

THE NEW HERCULES.—The Pontifical Academy of Archæology has decided that the colossal statue of Hercules, found beneath the ruins of the Theatre of Pompey, shall be placed in the Vatican, and that it shall bear the title of the *Ercolo di Mastai*, in honour of Pius IX. It is a pity that the name by which it is to be known does not rather indicate its origin.

PUBLIC MONUMENTS.—The Emperor of the French has decided that a statue of Dupuytren, the celebrated surgeon, shall be raised in Pierrefeu, in the depart-

ment of the Haute-Vienne, the place of his birth. A commission has been appointed, and special application will be made to the learned societies. The Comte de Cardailhac, director of buildings for civil purposes, under the Minister of State, is appointed receiver of the subscriptions and treasurer.—The statues of Cavour and of Italy which are to surmount the monument to be raised in Milan in memory of the great minister of Victor Emmanuel, are now on view at the royal foundry in Florence. The sculptors are Antonio Tantardini and Odoardo Tabacchi, and the casting in bronze is entrusted to Clemente Papi.—Four statues were recently set up in the grand vestibule of the Royal University of Naples, representing Pier delle Vigne, Thomas Aquinas, Jourdain Bruno, and John Baptiste Vico. Professor Settembrini seized the occasion to present a plaster bust of Humboldt, from a model by Rauch, and proposed that a subscription should be entered into amongst the professors of the University for its execution in marble. The suggestion was taken up warmly. The sculptor Angelini made a present of a fine block of marble, and a young artist, named Uriele Vitolo, was entrusted with the execution of the work.—A grand monument is about to be raised to Catherine I. in St. Petersburg. A statue of the Empress, which is said to be particularly fine, is to be placed on a pedestal decorated with figures of the following celebrities of the period:—Derjavin, Madame Dashkoff, Betski, Bezborodko, Roumiantzow, Potemkin, and Souwarrow. The whole is to be the work of Mikechine, whose original design was to be seen at the London Exhibition of 1862, where a medal was awarded to the artist. Considerable alteration, however, has since been made in the plan and statues. The cost of the whole is estimated at 250,000 roubles.

Manufactures.

AMMONIACAL GAS AS A MOTOR.—M. Ch. Tellier has conceived a new and curious application of this gas. He proposes to take advantage of its peculiar properties, and use it, in certain cases, as a substitute for steam. The qualities referred to are, its great solubility in water, its easy liquefaction, its power of supplying motive power at the ordinary atmospheric temperature, the capability of its vapour being superheated without too great an increase of the temperature, the possibility of re-collecting it by solution, and the faculty of extracting the latent heat from its vapour, after the latter has been employed, and transmitting it to that which is about to be used, by the simple act of dissolving the gas in water. With a given quantity of ammoniacal gas and three times its weight of water, says the inventor, the whole of the former may be vaporized and used as a motive force with a pressure of 8 to 10 atmospheres, and the action would be constant because the latent heat required for the vaporisation would be constantly reproduced by the caloric released by condensation. So that liquid ammonia is said to supply an instantaneous and practical means of obtaining a motive vapour. With about 22 lbs. of the liquid, we are told, the force of one horse may be obtained for an hour. The inventor does not pretend to place this system in competition with the steam-engine, but only where the production of steam would be impracticable and inconvenient. For instance, he says, "an omnibus, drawn by two ammoniacal horses, only need carry about 40 lbs. of liquid ammonia and 120 lbs. weight of water. This would supply a simple motor, without smoke or steam, instantaneous in its action however long and frequent were the stoppages, and with an economy over horses of at least 75 per cent." M. Tellier also recommends his invention for steep inclines on railways, tunnels, mines, and other places where heat cannot be tolerated.

TOBACCO MANUFACTORIES IN FRANCE.—It is well known that the manufacture of tobacco, snuff, and cigars is a State affair in France, as in some other countries. There

are seventeen establishments of the kind in France, two in Paris and one in each of the following towns:—Bordeaux, Châteauroux, Dieppe, Havre, Lille, Lyons, Marseilles, Metz, Morlaix, Nancy, Nantes, Nice, Strasbourg, Tonneins, and Toulouse. The total number of persons employed in these seventeen factories is stated to be nearly 17,000, the two establishments in Paris alone having nearly 3,000. The amount paid for salaries and wages was, in 1862, £235,256, and adding to this the sums paid to agents and others, the total expenses of the tobacco manufacture in France amounted to 11,380,949 francs, or, in round numbers, £455,238.

Obituary.

Mr. J. B. NEILSON, the inventor of the hot blast, died recently. This invention may be said to have revolutionised the iron trade, and added largely to the sources of wealth and happiness throughout the world. The west of Scotland has especially benefited from the stimulus which this invention has given to the development of its mineral treasures during the last 35 years. In 1828, when the hot blast was invented, the produce of the smelting furnaces of Scotland was not more than 29,000 tons per annum; in 1864 the produce was 1,160,000. In 1828 the average selling price of a ton of pig iron was about £7; while in 1864 it was £2 17s. 3d. A large, if not the largest, portion of this increased production and money saving is to be traced more or less directly to the general adoption of the hot blast process. Even before Mr. Neilson's patent expired in 1842, the process had become general in all the iron-producing districts of Europe and America, and was even practised in India. Mr. Neilson was a native of Shettleson, near Glasgow. He was born in 1792, and was brought up as a working mechanic. Mr. Neilson had been twice married, and has left a numerous family.

Notes.

EXHIBITIONS.—The acclimatisation of exhibitions seems to be complete. Shows, artistic and industrial, temporary and permanent, are announced in all directions. Rome is to have a general Exhibition this summer. Cologne announces an international one of agriculture and objects of domestic economy, to open on the 16th of May in this year, in the grounds of the Horticultural and Floral Society, established close to the town, under the patronage of the Queen of Prussia. The Crystal Palace of Oporto is announced to open on the 21st of August; the spot selected for this building is a commanding eminence, from which the Douro may be seen falling into the ocean. On the opposite side is the chapel erected to the memory of King Charles Albert, father of Victor Emmanuel, who died at Oporto. To the east, but at some distance, are the mountains of La Beira, the famous vineyards of Douro, whence comes the Duke of Wellington's second title. Attached to the property of the Exhibition Society is a park, which belongs to the house in which Charles Albert died. The spot selected is about twenty minutes' walk from the town of Oporto, which will shortly be connected, directly, by rail with the Spanish and French lines. The Industrial, Agricultural, and Horticultural Society of the Department of the Haute Marne, announces an Exhibition for the month of May. This department, which is a six hours' journey from Paris, is the centre of the metallurgical industry of the east of France, and, doubtless, the great iron works of Champagne, Lorraine, and Franche-comté will be well represented. The cutlers of Nogent, who have a high reputation, and employ upwards of six thousand workmen, will make a good show. This is not the first Exhibition of the kind that has been held at Chaumont, but it is expected to be on a much larger scale

than those which have preceded it. It is said that a company has been formed at Brussels with the view of establishing, at Laeken, a permanent exhibition of objects of industry and works of art. To this may be added the reminder, that Exhibitions of Fine Arts open during the two coming months at Bordeaux, Pau, and Glasgow.

BRITISH ASSOCIATION.—A public meeting was held recently in Dudley, called by the Geological Society, to consider what steps should be taken in South Staffordshire for receiving in a suitable manner the members of the Association at their visit to Birmingham in September next. It was stated at the meeting that one of the most interesting features in the district would be the manufacture of iron, and the geology of Dudley. It would be very desirable that the committee formed in South Staffordshire should prepare a full report on the state of the district iron trade, and on the coal-fields. It was hoped that the district would co-operate in obtaining papers for the various sections bearing on the scientific features of the locality. Mr. Frederick Smith, agent to the Earl of Dudley, announced that his lordship would have every accommodation for the Association on their visit to Dudley; and his grounds, caverns, collieries, and ironworks would be thrown open for their inspection. A committee was formed to make the necessary arrangements for the reception of the Association, and a resolution was passed, requesting the manufacturers of the district to subscribe towards the fund to defray the necessary expenses.

FRENCH ACADEMY OF SCIENCES.—There has been a sharp struggle of parties with respect to the filling the vacant seat in the section of mechanics in the above academy, and a curious departure from the ordinary mode of procedure. Three names were put forward in the usual way, when that of Colonel Favé, the Aide-de-Camp of the Emperor, was proposed, and added to the list by a vote of 31 in a meeting of 58 members, whereupon that of M. Léon Foucault was also proposed and adopted by 36 out of 49 votes. The speech of M. Delaunay, who proposed Colonel Favé in the secret committee, having been printed and distributed by its author, five of the members moved a resolution that the whole of the discussion should be given to the world. It is said that Baron Charles Dupin, M. Combes, and the Generals Piobert and Morin, made a vigorous opposition to the colonel's nomination. The result of all this has been the defeat of that gentleman, and the publication of the fact that he was in reality the representative of his Imperial master. As regards the claims of the two candidates already named, it is said that the discussion has established the fact that the idea of the rifled field artillery was really the Emperor's own, and not that of Colonel Favé, and that the latter was only the author of a faulty sketch for the siege guns used at the Battle of the Alma; and that the plating of ships of war was the work of the commission headed by M. Dupuy de Lôme, the chief constructor of the Imperial Navy, and M. Garnier. The claims of the colonel's opponent, M. Léon Foucault, are well known to the scientific world; his great telescope, and various apparatus for astronomical and other observations, have earned him an European reputation. M. Bertrand and M. Le Verrier supported his claim to the vacant chair, and after several divisions and one adjournment, M. Léon Foucault obtained a majority. Before, however, he takes his seat in the academy, his election will have to be confirmed by the Emperor, to whom all members elect are presented in person by the officers of the academy.

Correspondence.

PROPELLING TRAINS ON LINES WITH FREQUENT STATIONS.—SIR,—My suggestion as to motive power is so evidently misunderstood by your correspondents, that I beg to add some remarks on the subject. The argument of those

gentlemen appears to be that the present average speed (about 14 miles when travelling) cannot be improved without getting too rapidly into motion. I cannot agree to this proposition, but believe that great improvement can be made (certainly up to 20 miles) without undue acceleration, and that existing companies will be compelled ultimately by competition to adopt a superior rate of travelling. There is nothing said in my paper to justify the supposition that I propose to put trains suddenly into motion, as the acceleration now made by locomotives in descending gradients, if adopted generally, would make the average above 20 miles per hour. I cannot doubt but that companies having frequent stations, will give due consideration to the subject, and ascertain whether responsible mechanical engineers will lay down and maintain machinery on the plan proposed, and guarantee an improved rate of travelling at reduced cost.—I am, &c., PETER W. BARLOW.

LONDON MUD.—SIR,—London dirt is proverbial, and I have heard countrymen go further, and say that Londoners love dirt; and, having been recently in London, I begin to believe I may say that I skated from Charing-cross to Blackfriars, even by the door of the Society of Arts, and no attempt appeared to be made, except here and there, to remove the accumulated mud. Why is this? Can it not be removed? I believe it can; but if there be a difficulty, pray ask the Council to offer a prize. My own lucubrations, being caught in a heavy shower to-day, teach me that it can be done, and that that very thrifty dame, Nature, shows us how. Well, then, what I would propose is, that we should imitate her. The rain runs from the centre or highest part of the road to the gutter, and from the shop door to the same gutter. Now, if a simple iron pipe, perforated right and left with holes, ran along the centre of the road, and another in front of the doorway or under it, in either case very slightly raised above the road level or pavement, the whole might be very cleanly washed every morning. Further, if the pavement or stones were bedded in asphalt, much accumulation of dirt would be avoided, but without this, if duly and persistently washed day by day, the evil would be overcome, and London be as clean and comfortable as the well-washed portion of its population is. Excuse these hasty thoughts of a sufferer, and if possible turn them to account.—I am, &c., ANTIQVOPHILOS.

Announcements by the Council.

CANTOR LECTURES.

The Second Course of Cantor Lectures, the subject being "The Applications of Geology to the Arts and Manufactures," by Professor D. T. ANSTED, M.A., F.R.S., is now being delivered on Monday evenings, at Eight o'clock, as follows:—

FEB. 13TH.—LECTURE 2.—On Natural and Artificial Springs, and on the various Sources of Water Supply for Towns and Cities, in connection with the Geological Structure of the Vicinity.

FEB. 20TH.—LECTURE 3.—On Mineral Materials used for the Purposes of Construction: Plastic and Incoherent Materials (Clays and Sands).

FEB. 27TH.—LECTURE 4.—On Mineral Materials (continued): Building Stones and Slates, and their Relative Value under given Circumstances of Exposure, and on Methods of Quarrying.

MARCH 6TH.—LECTURE 5.—On Stratified Deposits of Minerals, as Coal and Iron Ore, usually obtained by Mining Operations, and on Mining Methods for such Deposits.

MARCH 13TH.—LECTURE 6.—On Metalliferous Veins or Lodes and their Contents, and on the Extraction of Metalliferous Minerals from Lodes.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture. For this purpose a set of Tickets has been sent to every member.

FINAL EXAMINATIONS—BOTANY.

In addition to the Prizes in this subject offered by the Society of Arts to candidates taking a Certificate of the First Class, the Royal Horticultural Society offers five prizes, of £5, £4, £3, £2, and £1 respectively, to the five candidates being gardeners by profession, who, taking any grade of certificate in Botany, obtain the highest number of marks in that subject at the Final Examinations in April next.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

FEB. 15.—"On the Claims of Authors and Inventors to Property in and Protection for Designs and Inventions first published at Industrial Exhibitions." By THOMAS WEBSTER, Esq., Q.C., F.R.S.

FEB. 22.—"On the Municipal Organisation of Paris, especially with reference to Public Works." By GEORGE R. BURNELL, Esq., F.G.S.

INSTITUTIONS.

The following Institutions have been received into Union since the last announcement:—

Rawtenstall Mechanics' Institution.

Tottington (near Bury) Mutual Improvement Society.

Proceedings of the Society.

CANTOR LECTURES.

SECOND COURSE.—FIRST LECTURE.—MONDAY, FEB. 6.

Professor ANSTED commenced by stating that he proposed, in these lectures, to introduce the subject of the various practical applications of geology. He was aware of the difficulties; for, on the one hand, the facts were so numerous that if merely enumerated and tabulated they could not all be placed before his audience in the time at his disposal; and, on the other hand, if he were to generalise without facts and statistics, he could not expect that the great importance of his conclusions should be appreciated. He considered that an account of the working out of the great theorems of geology, and their bearing upon agriculture, architecture, engineering of all kinds, and mining of all kinds,—their influence on the progress of the arts of construction, and on the discovery of the material of which things are constructed, could not want interest, and need not be useless because it was brief. In treating of the applications of geology, it would be convenient to take advantage of certain natural divisions which the subject offers. The earth was both the place itself on or within which everything was done, and it yielded all the material by which everything was done. We had to employ the earth as it was presented to us by nature, and to do so we had to discover and remove from the earth the means of using this same earth to

advantage. On the applications of geology, that which had reference to agriculture was the one to be considered this evening. It was one involving many details and many principles. On the part of those who entered on the subject, a certain knowledge of geology must be presumed, but the lecturer thought it well to lay down, in a few words, in mere outline, a statement of those facts that were chiefly concerned in its reduction to the use of common life. The surface of the earth, in the cultivated parts of a country, consisted of vegetable soil. In parts where the soil was barren this might be sand or stones, but it concealed the rock. In a fertile district only a very small proportion of the surface exposed the rock to view. In England, almost everywhere on the east side of the country there was soil of some kind; while on the western extremity there were large tracts of barren rock. Every country had its own *faunes* in this respect, and even where soil existed its thickness and general character were very variable. Whatever the thickness might be, however, there was always a termination to the soil, and below it was a subsoil partaking of a mixed character, between soil and rock, while below the subsoil was the rock, often exposed in quarries and railway cuttings, or in fragments brought up when water was sought for. Even the channel cut through by a stream, however small, would often be found to give a geological section. Rocks were of various kinds, but the varieties might be included within certain general and familiar terms. Such were limestone, sandstone, clay, granite, basalt, slate, &c. Mixed fragments of these formed gravel when loose, and conglomerates or pudding-stones when cemented together. More minute fragments ground to powder were sand. Of these, some were stratified, others unstratified. So, again, some were aqueous, others igneous. Others, again, and these were very numerous, might or must have been formed with water, but were now so far changed as to have lost their aqueous character. These were metamorphic. Limestone was an aqueous rock, and stratified. Basalt was an igneous rock, and might or might not be in strata. Slate was an aqueous rock, but metamorphic. Granite was metamorphic, and generally unstratified. Stratified rocks were generally tilted, and it was even possible that beds once horizontal might be actually inverted, and made to dip the wrong way. Rocks occurred in series. Often a multitude of stratified rocks were found in the same district, some of them being much more tilted than others. Stratified rocks were often interpenetrated by those that are metamorphic or igneous, but sometimes the metamorphic and igneous would alternate with the aqueous. Such were some of the simplest and most significant facts of geology bearing on those practical questions to be considered in these lectures. Rocks were the mineral constituents of the earth beneath any vegetable soil that might have accumulated upon them. They would yield to the chemist a ready account of their composition, and to the student investigating them for that purpose, a clear outline of the mechanical changes they had undergone; while they were often sufficient to enable the geologist to determine a complete outline of events, and a history of changes that may have taken a long time to complete. Owing to the mixed origin of rocks, it had happened that most rocks were broken and fractured, the cracks being filled up more or less completely with minerals, generally crystalline. Every kind of vegetable soil was once rock, which had been broken down by degrees into fragments, until at last it was reduced to mud. The part of this process performed by the atmosphere was called weathering. Wherever rock was exposed to the air, it became weathered; and weathering meant ultimately a reduction to fine powder. On granite or quartz rock, a group of small lichens was seen to grow. These were insidious enemies, as, although they derived their nourishment chiefly from the atmosphere, and might be thought even to protect the exposed surface from the weather, they paved the way for destruction. That which they separated from the air became a

brown pulverulent mass, of *humus*, which afforded nourishment to larger individuals of the same tribe. Mosses succeeded lichens, and small crevices received their roots. Once inserted, these roots expanded, splitting asunder the rock. Other roots were thus enabled to penetrate yet further; and after a time the mosses were followed up by heather, grasses, and small shrubs; until at length there was attained a sufficient thickness of soil to enable trees to grow, thrusting down their rootlets in the crevices and making room for the admission of rain. Then frost coming, rending asunder the rock, which would fall into the valleys below, spread over the surface and being lost sight of, being washed away by the rain. In certain soils the underlying rock was found in situ, in angular fragments and recognizable; elsewhere the fragments were water-worn, and belonged to some distant mountain or hill. This transported material was more common than the other, for water had everywhere been at work. Thus alluvial soils were formed. The solvent power of water was a very important agent in weathering. On detached fragments of limestone, water and vegetation together acted as a drill. Of sandstones it dissolved the calcareous cement, or even the silica itself. Thus in a mixed rock, as basalt, great differences of composition existed between an unweathered and a weathered specimen, and in a particular case referred to, 65 per cent. of the soluble alkalies had been removed, 28 per cent. of the alkaline earths, nearly 20 per cent. of the silica, only 2½ per cent. of the iron oxide, and no appreciable quantity of the alumina. Productive soils were composed partly of mineral substances and partly of certain products of the decomposition of organic bodies. This latter portion was called *humus*. It consisted largely of carbon, and carbonic acid was mixed freely with the water that passed through fertile soil. Humus was not generally present in soils in large proportion, but was abundant in peat and moor soils. The mineral constituents of a soil were of two kinds: the one kind we might call earth, as being a disintegrated mineral substance, the other consisted of fragments of the rock from which the earth was derived. The latter we might call stones. The former rendered the ground arable; the latter increased the bulk of the soil and facilitated the action of rain and frost, but contributed nothing to nutrition. Clay, lime, and sand formed the staple of all rocks, and were the ingredients of chief importance in every cultivable soil. Clay was a silicate of alumina, capable of retaining a large quantity of water, forming with it a tenacious, compact, sticky paste, which was almost impermeable to water. Hence soil containing much clay was heavy and difficult to work, remaining wet when soaked, and caked at the surface, allowing the water to descend very imperfectly. Cold and wet places were formed underground when clay existed below a good vegetable soil, and the roots of trees and plants reaching this water were poisoned. Wet clay would contract on drying, cracks forming in it after drought. The changes that prepared a soil for sowing were then checked in such material, or were only enabled to come about slowly. Frost would break up the clods, and sand improve the quality; but a deep clay soil was very difficult to improve. Mechanical admixtures with ashes and soot, as well as with sand, were suitable to such soils. Clays contained much potash, some phosphoric acid, and lime. They would also absorb ammonia and aqueous vapour from the atmosphere, and fix the ammonia very effectually. They were thus regarded as powerful and rich. When slightly burnt they became mellow. In England clay lands had been effectually improved by various methods, and had become extremely valuable and fertile, especially for wheat crops. Drainage opened the way for the permanent improvement of clay soils. Clays were largely derived from felspars. Granite, gneiss, basalt, clay-slate, and other metamorphic and igneous rocks yielded little else than clay soils. Loam was clay mechanically mixed with sand. The quantity of free silica that might exist in a soil without removing from it

the usual characteristics of clay was enormously large. Sand was the least changed of all rocks by weathering. Sandstones were changed by the destruction of the cement that holds them together, but the actual particles changed only by mechanical abrasion. Sand was an accumulation of granules of quartz, lying loosely beside one another, leaving abundant interstices admitting the free passage of water. Water was only retained in sands near the surface in small quantities. Light soils, containing much sand, had a hot, dry nature, giving up moisture rapidly during warm weather, and being readily heated by a summer sun. So again, these soils were active but soon exhausted. When sand was present in an exceedingly fine mealy state it approached clay in its properties, forming a dense compact mass, and holding water. This transition was a very curious fact, and one often insufficiently regarded. Common limestone was a carbonate of lime, exceedingly soft, and readily acted on in the state of chalk, but harder and more stony in the coillites and other building stones. Limestones would work up into soils red in colour, and cracked and broken by weathering near the surface. Magnesian limestone consisted of a carbonate of lime and magnesia, the proportions being variable. It was less capable of supporting abundant vegetation than common limestone. All limestones were permeable to water, and contained a considerable per-centage of it. Chalk was especially absorbent, and acted like a sponge. A calcareous or lime soil was soft to the touch, standing in this respect midway between clay and sand. It would absorb and retain water, but would not become sodden. Its tenacity was greater than sand, but less than clay. It would shrink much less than clay, but would not crack. It would diminish the tenacity and humidity of clay soils, rendering them more porous, more accessible to air, and warmer. Where, however, lime greatly preponderated, the soil was poor and hot; but these characters were readily altered by the admixture of clay and humus. Every soil would support some vegetable growth, much of the difference depending on the mechanical condition of the soil, and much on the chemical composition. Both were due to the underlying rock. To produce a productive soil, in the first place, certain conditions must be avoided. First, too great cohesion. A soil, otherwise productive, might be rendered unproductive if washed by rain into hollow bottoms, where it would cake into a solid, impenetrable mass. Secondly, want of cohesion. A soil might be too coarse, too loose, and too open. Thirdly, poisonous ingredients. This cause was rare, but it existed. The salts of lead and copper were absolutely poisonous in all proportions. Sulphate of iron was also poisonous, and alum might be regarded in the same light. Lastly, the excess of some nutritious ingredients. Thus, common salt was used as a mineral manure, but salt water would entirely destroy vegetation. Mineral acids also interfered with growth, and would destroy vegetable life, if in too large proportion. To make a soil productive, it should possess, first, a soft consistence, unchanged by the operations of tillage. In the next place, the soil must furnish the plant with food essential to its existence in a digestible form. Among the important mineral constituents of a soil were—phosphoric acid, potash, lime, and magnesia. The quantity of these was variable, but the following statement of the limits would be useful as a guide, being given on the authority of Dr. Stöckhardt, a Saxon chemist:—

An Acre of Land, six inches deep, would contain about:—	Maximum.	Minimum.	Mean of predominating Rich Soils.
	Pounds.	Pounds.	Pounds.
Phosphoric acid	12,000	150	2,500
Potash (total quantity).	53,000	1,500	22,000
Soluble potash	15,000	750	3,500
Lime and magnesia ...	145,000	900	30,000

This estimate would show the relative importance of these substances. The most important was phosphoric acid, for without it nourishing food could not be grown and ripened. Of other substances, sulphuric acid must be present, but of it there was generally no want. Silica also was essential and was always present. To learn the proportion needed we must refer to the constituents of the ashes of plants. These would show that some species contain in the ashes of one thousand pounds of dried plants only two pounds of lime and magnesia, half a pound of potash, and only a quarter of a pound of silica. Of meadow grass, however, the ashes contained sixty-four times as much phosphoric acid, thirty-four times as much potash, four times as much lime and magnesia, and eighty times as much silica, as in the case of conifers; while wheat contained the same proportion of silica as grass, but much less phosphoric acid, potash, lime, and magnesia. Particular soils were thus favourable for certain crops; forest land that had been so from time immemorial, and was put under another cultivation, was rich; certain soils, unfavourable for particular crops, might once have been the contrary. A productive soil should be composed of nearly equal parts of the three earths—sand, clay, and lime; it should contain decomposing vegetable and animal matter; it should imbibe moisture and give it back to the air without much difficulty; it should have depth sufficient to permit the roots of plants to sink and extend without coming to rock, to water, or to some injurious earth; the subsoil should be moderately porous, and should be able to improve the soil by mixture with it. The proper proportion of the various earths might vary from 50 to 70 per cent. of silicious matter, 20 to 40 per cent. of clay, and 10 to 20 per cent. of calcareous matter. The earth would bear a constant succession of crops of the same kind, if the mineral ingredients removed by one crop were supplied in the same state from year to year. But this could only be done as the result of a nice calculation, and by careful and systematic farming. As a remarkable instance of the successful use of mineral manures in rendering an ordinary soil capable of bearing, the lecturer quoted the experiments carried on at Rothamsted by Mr. Lawes and Dr. Gilbert.* The general result was that the average annual yield, without manure, was much the same over the whole period (of twenty years); that where ammonia salts and all mineral constituents were liberally supplied every year the produce of corn increased and that of straw somewhat diminished; and that where an excess of every constituent required by the crop was annually supplied, by farmyard manure, the rate of increase from year to year was not so great during the later as during some of the earlier years. Analyses of soils were very suggestive. The lecturer mentioned the component parts of some extremely rich soils, but he pointed out that few ordinary soils contained within them such great natural resources. Many that were very valuable under careful management and continued culture, would be almost valueless if left to themselves. The treatment that would best succeed in improving a soil must depend on the subsoil, the climate, and the facilities that exist for obtaining at a reasonable cost the required mineral manures. Among mineral manures the most important were those which supply phosphorus and nitrogen to the growing plant or ripening seed. These were especially necessary for food plants. The want of nitrogen was usually supplied by animal manure; but this was costly, and not always obtainable at the right time in proper quantity, and in the best state. Nitrate of potash, or saltpetre, was known to be a highly efficacious substitute, as well as *cubic nitre*—a nitrate of soda, of which very large quantities were obtainable. This material appeared to be the best and readiest means of communicating nitrogen to growing plants. It was now many years since attention was directed to the phosphates of lime from Estremadura, in Spain, and Dr. Daubeney, ac-

* See *Journal R. Agricul. Soc.*, Vol. xxv.

accompanied by Captain Widdrington, undertook to decide whether it could be economically worked and conveyed to England. They found a bed consisting of several bands of tolerably pure phosphorite. The thickness of the purer part was about 3 feet, and it was traced on its line of outcrop for about two miles, but the distance from any place at which it could be shipped for exportation, and the cost of transport, rendered its existence useless for practical purposes. Other places were mentioned where this substance had been obtained. Limestone and gypsum were occasionally used as mineral manures. Much more usually, marling, manuring with mud, and warping or bringing on the surface muddy water, and leaving it there to deposit a slime, were resorted to. Another important department of practical agriculture was drainage. It was impossible to exaggerate the importance of water, but it was desirable to regulate its application, and remove it when in excess. Drainage performed this by acting both upon and below the surface, and allowing the water to run off by natural channels. The effect of ploughing, was to disturb the ground and expose it to the air, but it was not till drain-pipes were laid that the soil could be said to be available for high cultivation. Drainage was chiefly important in heavy clay lands. Geological maps were most useful in regulating draining operations.

TENTH ORDINARY MEETING.

Wednesday, February 8th, 1865; EDWIN CHADWICK, Esq., C.B., in the chair.

The following candidates were proposed for election as members of the Society:—

Edwards, Henry, 53, Berkeley-square, W.
Lambert, Charles, 3, Queen-street-place, E.C.
Runtz, John, Burlington-house, Stoke Newington, N.
Saunders, Samuel, 22, Sussex-gardens, Hyde-park, W.

The following candidates were balloted for and duly elected members of the Society:—

Bonnerjee, W. C., 108, Denbigh-st., St. George's-rd., S.W.
Hill, Frederic, The General Post Office, E.C.
Peckett, George, 10, Abenden-park, Highbury, N.
Perkins, Houghton, 25, Mortimer-street, W.
Robinson, Noel Hooke, 6, Great Queen-street, S.W.
Rodger, Captain William, R.N., 9, Shawfield-street, King's-road, S.W.
Sancton, Philip, 23, Cumberland-ter., Regent's-pk., N.W.
Smith, Colonel John Thomas, R.E., 27, Cannon-st., E.C.
Stone, George Graham, 78, Holland-park, W.
Sudlow, John J. J., 8, Manchester-buildings, S.W.
Thompson, Thomas C., 43, Belsize-park, N.W., Sherburn Hall, Durham.
Tomline, William, 5, Whitehall-yard, S.W.

The adjourned discussion on the paper, "London Sewage from the Agricultural Point of View," read by John C. Merton, Esq., at the last meeting, was resumed by

Professor VOELCKER, who said he thought the views expressed in the paper of Mr. Morton had received the general approbation of all who had given a thoughtful interest to the subject of sewage in its agricultural bearing. They were called upon to discuss it from this point of view only, for although there had been a great many discussions on the subject of sewage, yet he contended that in its agricultural bearing it had not been sufficiently ventilated. People had devised schemes without inquiring, in the first place, into the character of the soil which was fit for the reception of the sewage, and hence resulted such great diversity of opinion as to the quantity of sewage which might be appropriately applied to land, some contending for small and others for large quantities. In his opinion this question could have been settled long ago if the character of the particular land

to be treated had been carefully kept in view. Some regarded sewage as a universal manure, fit for every kind of soil, and applicable to every kind of crop. Though he was far from contending that sewage should be applied to grass land alone, he agreed with Mr. Morton that this should be its principal application, but there were cases in which he thought it might be applied to root crops, especially to mangels, which, being provided with a very large leaf surface, evaporated a considerable quantity of moisture, and would appropriate to itself a large amount of sewage. But in the first place they had to inquire into the character of the soil which was most appropriate for the reception of the sewage. He knew perfectly well that there was land in England that did not stand so much in need of manure as of thorough deep cultivation; these were soils which had such immense stores of mineral food that it only required to be developed by the application of special manures in order to produce very large and remunerative crops. It was on such rich clay lands, he believed, sewage never had been and never could be applied with advantage. They had clay soils in this country which were ungrateful for every description of manure, but were most grateful for the steam plough, draining, subsoiling, and all other modes of deep cultivation: and the reason why sewage did not answer for those rich clay soils was, because the fertilizing substances supplied to the soil by the sewage were insignificant in comparison with what the soil already contained. Besides, if a large quantity of water was applied, the excess of moisture did more harm than good to the growing crops. With regard to experience in the application of sewage to clay soils, he could name several landed proprietors who were great enthusiasts for the application of liquid manure, and who had constructed large tanks, and had most thoroughly carried out the experiment, not only on grass land, but on root crops, but had generally signally failed. But let them look at the other extreme. They found in some cases soils so poor, that they required large stores of every kind of mineral and organic matter to be supplied, and these were the soils on which, no doubt, sewage might be used with great advantage. In fact, it might be laid down as a rule that the poorer the soil was, the more successful the application of sewage was likely to be. In the case of such soils, too, they were not to use merely what appeared sufficient on calculation, but something like a hundred or two hundred times as much. Let them here again take actual agricultural experience for their guide. They found that on some soils they could raise very heavy crops of turnips by the application of a few cwts. of guano per acre, three or four cwts. of superphosphate, and a moderate dressing of farm-yard manure, whilst on poor sandy soils, 20 tons of farm-yard manure was considered a moderate dressing, being further augmented by a considerable quantity of superphosphate as well as guano. The quantities of manure to be put on the land should thus in a measure be regulated by the character of the soil. They knew they could raise, on moderate land, good crops by the application of a few cwts. of superphosphate and a few cwts. of guano, while on poor soil they required the same quantity of artificial manure, in addition to 20 tons of good rotten farm-yard manure. In this 20 tons of farm-yard manure they had an amount of phosphoric acid that could only be supplied by 14 cwt. of Peruvian guano; or if they wished to supply the amount of ammonia contained in these 20 tons of farm-yard manure, they would have to use 18 cwt. of guano; or, again, if they were to apply, in the shape of guano, the amount of potash contained in 20 tons of farm-yard manure, they would require to use 1½ ton of Peruvian guano; but no farmer in his senses would think of applying even 14 cwt. of Peruvian guano. If half that quantity were used on some soils, it would kill the crops outright. Hence they saw the poorer the soil was, the larger was the quantity of manure that should be put on the land, and that the quantity they took away in the crops, when harvested, was by no means an indication as to the quan-

it ought to be incorporated with the soil. There were many medium soils on which it would be to apply sewage with advantage, but then the ought not to be so excessive as in the case of the lands, which would swallow up almost any amount of sewage with profit. These were matters of experience, and I thought, if they wished to make the best of London sewage, they ought to institute a very extensive series of experiments on the application of the sewage to lands of various degrees of fertility. He believed that much good would result if the character of the land were first taken into consideration than had hitherto been the case. This was the point which he wished to bring prominently before the meeting.

Mr. SIDNEY said, in discussing the question of the application of London sewage to land, two points were to be considered, viz., quality and quantity. The latter was the more important, as it could hardly be made intelligible in terms of tons or cubic feet, the daily supply being sufficient to cover an area of about 80 acres three feet deep, and that supply required to be disposed of day by day. As to the quality, it was not what they formerly had, diluted with merely twelve gallons of water to a gallon of sewage, but more nearly with forty or fifty gallons. Now they were now past the time for theorising on the subject, inasmuch as they had twenty years' practical experience. He found that up to the present there were nine towns in which attempts had been made to apply sewage to agricultural purposes—viz., Croydon, Carlisle, Edinburgh, Malvern, Taunton, Rugby, Watford, and Worthing. These towns had, upon the whole, the most successful results obtained of this application. At Edinburgh, large quantities had been applied to poor sandy soils with good results. It might be that in some degree, as was said by Lord Robert Montagu, it was wastefully applied, but in the towns he had enumerated the success had been so great as to induce other towns to imitate their example, and, at all events, to get rid of a nuisance if it did not make profits. At Alnwick, which was in a district subject to a very heavy rainfall, the use of sewage irrigation had been abandoned by the farmers. He did not consider that an argument against the system, but it rather pointed to the right mode of application. At the outset the application of the sewage by means of the pipe and hose system was generally in vogue.

The attempt was made to pump up everything; and those who were most enthusiastic in that system had abandoned it in favour of the Edinburgh meadow system, while the application of the sewage had been confined to grass crops, to the almost entire exclusion of attempts to apply it to cereal crops. One great reason for that was, perhaps, to be found in the fact that grass was too valuable and important a crop to the farmer to be the subject of experiment. With fair dressing and an average amount of rain, the farmer was pretty sure of a good wheat crop; therefore, though the application of sewage to the young crop of wheat would be beneficial in rare cases, the farmers would not incur the expense of such arrangements for this purpose.

Mr. SIDNEY read a return of the results obtained in the nine towns he had enumerated, which showed that, in most cases, the application of sewage was profitable, the system in favour being that of surface irrigation to grass. The sand jet had been generally discontinued. At Worthing, the sand jet was not yet in operation; but they were under the management of Mr. Rawlinson, who, after great experience in surface irrigation, was about to apply the sewage of a town of 7,000 to an area of about 400 acres. He had abandoned the hose and jet system as an expensive process, and high no satisfactory results could be looked for, and had adopted the open meadow system, applying it to sweet herbage only. Then, again, on this subject they had the roughly practical opinion of Sir Joseph Paxton, who was that they must be satisfied with securing a certain amount of good out of the application of sewage

under special circumstances, without expecting it to be universally applicable. His experience was that he could place the sewage made by 250 persons over an acre of sandy land in a year, and that with very great results as to the growth of plants. Sir Joseph Paxton also stated before the Committee that he had not the slightest notion that small dressings could ever be successfully applied with London sewage. Next, he came to the practical experience of the Earl of Essex, in respect of the sewage operations at Watford, who, in his evidence, stated that he began using the sewage of Watford under the impression that that would be sufficient to irrigate 210 acres, and he underpiped that area of land. The quantity of sewage he obtained, however, was about 60,000 or 70,000 tons a year, and this he now applied to only 10 acres of Italian rye-grass and 35 acres of meadow grass. He put 5,000 or 6,000 tons a-year to each acre of Italian rye-grass, and 600 tons on each of the 35 acres of meadow. After hearing such opinions as these, he (Mr. Sidney) thought they could place but little weight on the opinion expressed by Mr. Walker at the last meeting, that 720 tons a year per acre was a proper application of sewage—an opinion with which Mr. Walker's tenants entirely disagreed. On this subject they had also heard the opinion of his friend, Professor Voelcker, than whom no man more possessed the confidence of the farmers of England. Without disrespect to Mr. Walker, he might say that his absence from this country during a great part of the time these experiments were being made at Rugby, did not qualify him to give an opinion which was entitled to equal weight with those of the practical men whom he (Mr. Sidney) had quoted: and two of Mr. Walker's tenants had told him personally that they regarded the small application of sewage as of no use whatever. Again, Lord Robert Montagu referred to the evidence of Mr. Mechi in favour of small dressings in opposition to what his lordship regarded as the profligate employment of sewage on the part of Mr. Lawes, but he (Mr. Sidney) challenged any one who had visited Mr. Mechi's farm to say that any instance was there shown of the value of liquid manure; because, he ventured to say, Mr. Mechi had never grown a good crop from his liquid manure solely—he had been obliged to use solid manure as well. There was another distinguished name he might mention, viz., Baron Liebig, who had written a letter in the newspapers, telling them that after twenty years' experience on the subject of sewage manure, they were all wrong, and that good farming could be only obtained by small dressings. Now, although Liebig was a celebrated man, and a great chemist, he had never yet meddled with a practical question without being entirely wrong. Twenty years ago he denounced deep drainage for cereal crops, and recommended the introduction of a mineral manure that was to grow all sorts of crops, but it had been a failure. Since then he had informed the world that the system of farming pursued in this country had entirely exhausted the soil. He (Mr. Sidney) asked the farmers of England to be guided by the experience of practical men, such as he had referred to, rather than by the theories of enthusiasts. The view taken by Mr. Morton, as to the best mode of using London sewage, was, he thought, that which would bring as much profit as they could expect to derive, while relieving London of a great nuisance.

Dr. GILBERT said, having had a great deal to do with the Rugby experiments, he begged to be allowed, in the absence of Mr. Lawes, to say a few words in reply to what had fallen from Lord Robert Montagu and Mr. Walker at the last meeting, and also in reference to Mr. Morton's statement as the result of his observation of the Rugby operations. Mr. Morton had stated that, in passing over the fields, he saw one in which there was good sweet herbage, which had been fed off, and in another coarse, couchy grass, which had been mown. Now it was quite evident that Mr. Morton had not been informed of all the facts, or he would not have given the two different modes

of removing the crops as the sole reason for the difference in the character of those crops. The meadow which had been fed off had not received 1,000 tons of sewage annually, and had not supported one-third the stock that the more highly-sewaged and coarser herbage had done, whilst it had received repeated dressings of sewage, and the other none, during the whole of the excessively dry summer of last year. With regard to the change of herbage, it was well known by those who had had the largest experience in Edinburgh, that when they had sown fifteen or twenty different kinds of grass, in a few years, if the meadows were successful, and they gave large crops, they reduced them down to two or three plants, and they could not help it. It was, to a great extent, a question of quantity *versus* quality, and if the object was a large produce per acre, they could not have the complete herbage of a natural feeding pasture, and no one need attempt to get it. But Mr. Walker, in his evidence before Lord Robert Montagu's Committee, gave a statement as to the rules of action in the conduct of the Rugby experiments, and he (Dr. Gilbert) begged to state that both the rules and the practice were the precise contrary to those which were stated by Mr. Walker. Mr. Walker stated in his evidence that "there was a preconcerted system of watering certain plots at stated times, without reference to those times being just the suitable times for watering the ground. For instance, there were three plots in each field, and they were to be watered *seriatim* at given times, without reference to whether the grass was just then ready for watering or not. The grass was allowed to grow extremely rank, till it was quite dead at the bottom; then it was cut, and the dry stubble-like stalks left to dry a considerable time in the sun; then, and not till then, it was watered again, and took a considerable time to revive." Mr. Lawes being asked if he agreed with that statement, replied, "I do not say that such a thing may not have happened in the course of the last two years and a half, &c." Now he (Mr. Gilbert) would put it to any gentleman connected with agriculture whether it was possible to sewage any considerable portion of land and have no patches of overgrown crops at times? But on the strength of Mr. Walker's statement, and of the candid admission by Mr. Lawes, that the thing had occasionally happened, Lord Robert Montagu, in his remarks in that room last week, had stated that such was the prearranged rule in the conduct of the experiments. His lordship said, "not only was it wrong from the quantity of sewage put on it, but also from the precise rules which were laid down by Mr. Lawes himself, viz., that at such and such times the sewage was to be applied, and at certain periods the grass was to be cut. The grass grew very long and rank, and rotted at the roots, but Mr. Lawes did not cut it because the prescribed time had not arrived. At last the haymaking time came, and the grass was cut and carted away, while the rotted roots were left to bake in the hot summer sun. The land was parched and cracked, and all the grass worth having was killed." He (Dr. Gilbert) begged to say that, as to the alleged rule of the application of the sewage, there was just some plausible foundation in fact, but as to the alleged rule of cutting, there was none whatever. First, as to the rules of application of sewage. Looking to the fact that the supply of sewage was constant all the year round, and must be disposed of in the winter as well as the summer, it was arranged to apply the quantities fixed upon for each plot, within certain limits, evenly over the year, those limits being entirely dependent on the condition of the grass, always supposing that there was a supply of sewage to be had, which was not always the case, and this was no fault of the Commission. He (Dr. Gilbert) visited those fields during the period of active growth every few weeks, and it was his duty to get an exact record of the amount of sewage applied up to that date, and according to the state of the growth to give directions as to the quantity that should be applied during the next

few weeks, so as to give as far as possible the quantity they should receive in summer, at the most advantageous period for the grass. The rule was not to apply sewage when the grass was nearly ready for cutting, and to apply it again immediately the plot was cleared. But it had so happened, more particularly just at the entrance of Mr. Walker's field, where everybody saw it, that the land in that field, being in high ridges and very steep, it had been found very difficult to get the sewage on evenly, although a man was constantly employed in the field to secure that result; portions of the plot had grown very high, while the remaining portions were unfit to cut. Everybody knew that with the exercise of the utmost care it was impossible to get the sewage quite evenly on land so laid out, and that the result must be inequality of growth. From this accidental cause, therefore, it had occasionally happened that the grass on comparatively small portions of a plot had been allowed to remain longer than was otherwise desirable, because the rest of the plot was not fit to cut, and the sewage could not be applied again until nearly the whole was cleared. He therefore begged to repeat that the rules laid down, and practice almost uniformly followed, both as to the application of the sewage and the cutting of the grass, were precisely the contrary to those stated by Mr. Walker in his evidence, and by Lord R. Montagu at the last meeting. His lordship had also endeavoured to give the meeting the impression that Mr. Lawes' practical recommendation to the public was to apply as much as from 60,000 to 70,000 tons of sewage per acre, and his lordship put it to the meeting what was to be thought of the opinions of a gentleman who recommended from 50,000 to 70,000 tons per acre? and in contradiction to this his lordship quoted the statement of Mr. Walker, that on an average he only applied 750 tons per acre. Now Mr. Lawes had, in his evidence, about half a dozen times, distinctly stated that so far as his experience went, about 6,000 tons was the proper amount to be applied to grass land; but after giving that evidence over and over again, he was asked a question by the committee as to what he would do provided he had an unlimited supply of sewage for nothing? to which his reply was—"If I could have it for nothing, and put it on the ground, I would use 50,000, 60,000, or 70,000 tons per acre, or anything you could give me." It was, then, not as Mr. Lawes' recommendation to the public, as Lord Robert Montagu had with such want of candour endeavoured to persuade them, but simply with the view to getting the greatest possible produce per acre provided he were to have the sewage for nothing, that he said he would under those conditions use so large an amount. The following quotations from his evidence showed what was Mr. Lawes' practical advice on the point:—

4562. "I should think that, perhaps, 6,000 tons would be as much as I should wish to use upon an acre, if I could get a suitable district for it."

4565. "I should think 6,000 tons per acre, but it depends a great deal on a number of circumstances, &c."

4567. "Looking to the interest of both parties, I should say about 6,000 tons per acre; as a tenant, I should say 30,000 or 40,000 if you gave me the sewage. If you wanted to charge for it, I should confine myself to something about 6,000."

In conclusion, he (Dr. Gilbert) would ask, what would be the benefit to the ratepaying and urban populations of such unfair representations of evidence on this great question. He would ask, why Mr. Walker, the landlord at Rugby, was examined, whilst his tenants, the men who had lost the money on the small quantity and large area system, were not examined. The evidence of a farmer tenant had, it was true, been taken, and he, being a grazing farmer, and having lost much money by his sewage farming under Mr. Walker, his testimony was that sewage was not good for either grass or arable land. But neither of the present tenants (one of eleven years' experience) had been examined. Mr. Campbell being accidentally at the House on one occasion,

Lord R. Montagu offered to examine him if he wished, but it was for the chairman (Lord R. Montagu) to wish, and not for the witness, so he was not examined. Whatever use might be made of facts and evidence, and whatever schemes might be propounded, unless it could be shown that it was to the interest of the farmers to use the sewage, they would never be customers for it. The subject was essentially a practical one, and practical considerations could not be ignored; and he (Dr. Gilbert) was confident that if sewage could not be delivered on the land at an average of considerably less per ton the year round than had been proposed by sanguine and theoretical persons, the farmers would not use it, and nothing but loss, disappointment, and further postponement of the settlement of this question would result.

Mr. Alderman MASON said, to a certain extent, they must look for the same descriptions of prejudices on the sewage question as existed in the early days of gas and railways. It might be said to be the great question of the age, because it was quite clear the food of the people of this country depended on properly putting upon the soil human and animal excrement; and if he differed from gentlemen who advocated large applications of sewage to land, it was on this principle, that they had it in evidence that the farmed land of England, in its present form, received the excrement of about two sheep to the acre, and therefore when a sudden jump was proposed to what was equivalent to two or three hundred sheep per acre as the manurial provision it astonished farmers very much. Then there was another view of the question. If his calculations were right, it required the produce of 6,000,000 acres of land to feed the 3,000,000 population of London. It was true they had the difficulty—or what was said to be a difficulty—to deal with, that the manure contained in sewage was mixed up with a very large amount of water, and there naturally arose the question—first, whether the conducting of so large a mass of liquid to the land could be practically carried out with a profit; and, secondly, whether that additional quantity of rainfall—so to call it—would be injurious to the soil? The evidence of eminent hydraulic engineers was that they could raise 1,000 tons of sewage 800 feet at a cost of 13s. to 14s. If they applied that test to the cost of raising the whole of the sewage of London, he could not make it come to more than £500 per day. Now, if they were to believe Liebig, he told them, in his recent paper, that the sewage of London was of the value of £12,000 a day. Baron Liebig had recently addressed a paper to the Lord Mayor of London, for which the thanks of the Corporation would be voted to him, which appeared to exhaust the question as to the value of sewage and the most profitable mode of using it. Arguments had been employed against applying it to certain soils. His friend, Professor Voelcker, said some qualities of land required a great deal and others wanted very little of it; but if they looked at the area of 6,000,000 acres which he had referred to, they would find that nine-tenths of it was so poor that it would bear a double and treble supply of manure. But what did they propose to do on the principle of large applications? It was proposed to denude the great area of the land of the fertility which had been exhausted by the crop, and spread it over a smaller area in the immediate vicinity of the town. He cared nothing for any of the great rival schemes, but he spoke of this only as a great national question. Then came the question whether sewage was best for one crop or for another. The notion seemed to prevail at present that it was almost exclusively adapted to the growth of grass crops. But what did Liebig say on the subject? He said it was a great mistake to put it on grass crops at all, inasmuch as it supplied a large amount of fertilising properties which were not required for grass, but which would be of great value to cereal plants. Mr. Sidney had said that he (Mr. Mechi) knew nothing about sewage! Why, for fifteen years he had put

all the excrements of his animals and the sewage of twelve people in his house on his land, and if that, mixed with large quantities of water, was not sewage, animal and human, he did not know what was. The great mistake that had been made was applying sewage to slow-growing fine grasses in large quantities, when it should have been applied to rapidly-growing grasses of good quality. Italian rye-grass after sewage was so rich that they did not dare to give a full supply of it to young animals because it would kill them. He had lately had some calves die, and Professor Symonds told him the reason was the extreme richness of the Italian grass on which they had been fed. A practical farmer might regard the long, rank, strawy-looking hay from Italian grass as very poor stuff, but the men who fed horses and fat bullocks upon it said they had never seen their animals in such condition, even when they had the best clover hay, or the best meadow grass. This Italian rye-grass, which was a rapidly-growing grass, was particularly suited to large applications of moisture, for in the dry Midland, Eastern, and Southern counties, where there was not much rain, those who attempted to grow Italian rye-grass never got a second crop, because it absorbed and evaporated such a large amount of moisture; and he could understand perfectly what had been said by Dr. Gilbert, that the application of a large quantity of sewage would produce plants adapted to that large application, for by changing the application they changed the plant; the extent of moisture applied would actually regulate the kind of grass produced. He congratulated the Board of Works in having taken active steps in this matter, and the Society of Arts on the present discussion. It might take some time to settle finally the best mode of applying London sewage with profit and with good results, but in the meantime what he would guard the Board of Works against, was the parting for ever with that which they knew to be valuable. When such a man as Liebig stated the sewage of London to be worth £2,000,000 a year, minus the cost of application, it was a great mistake to give that valuable property away, except for a limited time and under certain conditions. The whole subject demanded serious attention, affecting as it did, not only the ratepayers, but the general interests of the country.

Mr. ROBERT RAWLINSON said he did not like to venture to say much on this subject, because he did not profess to have any intimate knowledge of agriculture, but it did so happen that he had had a pretty wide experience in the examination of districts where sewage works were being constructed, and where sewage application had taken place, and he had also necessarily paid some attention to the schemes which had been propounded for the application of the sewage of the metropolis to land. He had only a few minutes ago heard it intimated, by so high an authority as Mr. Alderman Mechi, that there was a probable advantage to arise to the metropolis in applying its sewage to large areas for agricultural purposes in small dressings. He could only say that, at the present moment, all the knowledge he possessed, and all the experience that had come to him, were in a directly contrary direction; and he also held that if large sums of money were raised by a company, and if the large works planned were attempted for the application of the sewage of the metropolis over hundreds of thousands of acres, he thought that it would only result in bankruptcy. To carry sewage over large areas necessarily involved two things, very expensive lifting power, and very expensive permanent plant below the surface for the so-called distribution. Where the application of sewage had been a success he found that it was in cases where it had been applied in large dressings, in the simplest possible manner, over comparatively small areas, with no price paid for it, and with very simple apparatus. In Edinburgh there was a very limited area, about 400 acres, receiving the refuse of a considerable portion of the city, which came down without any cost, without any fettering conditions as to how, when, or in what way it should be used. The

greatest possible results were thus produced from the land so treated; but in the town of Leith, clear-headed, calculating Scotchmen were going to expend £66,000 in sewerage the Leith district; and in the face of a rental of £35 an acre on the opposite side of the city, they were spending this large amount of money to carry the pipes on to the sea that the sewage might there be discharged. If any one thought they were wrong in this, and would like to take the sewage and make use of it, he (Mr. Rawlinson) would be happy to place him in communication with the Corporation of Edinburgh, who would be only too happy to let him have the sewage for nothing. Surely there was something in this, in spite of what Alderman Mechi had said about the necessity of taking the sewage back to the land. Was there no escape from the dilemma otherwise than committing themselves to an extravagant expenditure of money which would not be remunerative? How long would a scheme of applying sewage be carried on if it did not pay? They might manage by some means or other to utilise the sewage in a profitable manner, but to say that the sewage of London, which was the produce of 3,000,000 of people, should be applied over 6,000,000 or even 1,000,000 acres, was an absolute fallacy. In his opinion no such system could be carried out. Then, again, with regard to the mode of applying sewage, he would give them in a rough way the amount which it would cost to pipe the whole area. In round numbers, the cast-iron pipes they would have to lay down would cost a shilling per inch in the diameter for a yard in length. If they took the greatest and most successful examples of irrigation of which they had any knowledge, where large volumes of water had long been regularly poured over the land, producing really great results, such as in the northern parts of Italy, and in some parts of India, they would find that the whole of the water was distributed by canals, open carriers, and open runnels. It might be said that this was water, and what they were now dealing with was sewage, but if they had attempted to distribute the water by underground conduits of cast-iron, the works would have cost 24 times as much as they had done. Lord Robert Montagu had accused him of having given evidence before the Committee which was contrary to his opinions. He could only say that if in giving his evidence he failed to make his meaning clear it was from no dishonest motive; but his own belief was that his evidence and his opinions were in perfect accordance.

Mr. Bowring said he should be glad to accept Mr. Rawlinson's offer to be put in communication with the authorities at Leith, and would gladly take the sewage of that place. As they had heard so often, there were two modes of applying the sewage which were now being advocated by opposing parties, one that of small dressings over large areas, and the other large dressings over small areas. The mode, however, to be adopted was that which would enable the real value of the sewage to be fully made use of, giving the ratepayer his share in this value. For his own part, he believed the sewage was a very valuable property. Baron Liebig and others said that the sewage was worth about twopence per ton. Hofmann and Witt had adopted one method of proceeding, and Baron Liebig another, and yet they all three arrived at about the same result as to the actual value of the sewage. If the sewage were applied in such enormous dressings as 10,000 to 20,000 tons to an acre, as done at Edinburgh, and as proposed by Messrs. Napier and Hope, how was it possible to recover one-fiftieth part of its value? Liebig gave it as his opinion that sand was the last soil and grass the last crop to which sewage should be applied. He did not believe that the Board of Works had had the interest of the ratepayers of the metropolis at heart in what they had done, and it would be a source of satisfaction to everybody if that body would only come forward and allow their plans to be tested. All interested in the matter must be glad that Lord Robert Montagu had again taken the subject up, and that there would be an inquiry into

all the plans which had been proposed for the utilisation of the sewage, entirely without the assistance of the Metropolitan Board of Works.

Mr. HARRIS said there was one point which they seemed to have lost sight of, and that was that the Metropolitan Board of Works required the sewage to be taken away so as not to be a nuisance. Taking the sewage of the northern part of the metropolis at the quantity stated, it would be found that if it travelled at the rate of a mile and a half an hour, it would occupy a channel of something like 20 feet wide and 6 feet deep. Here was a small river constantly coming down to be provided for, and which must be dealt with as it came. This was a fact which materially affected the whole question. He would say nothing about the engineering part of the case, but the chemical question was a very important one. It was now generally acknowledged by chemists that the sewage was worth about 6s. per head of the population. It was best to speak of it as so much per head, because if the value per ton were given, the question of dilution entered so materially into the matter that it was impossible to get at anything like correct results. The sewage of Croydon, for instance, was diluted to twice the extent of that of Watford, and of course the intrinsic value of a ton in one case would be double that which it would be in the other. But what did Liebig say in his letter about the sewage in this diluted state? He said, "In the diluted state in which these elements are present in sewer water they are without any mercantile value." The ratepayers of London were the owners of this stuff in its rough state, and the farmers were the manufacturers who had to get the metal from the ore supplied to them by the ratepayers. As far as experience went, he found sewage so far from returning 6s. per head of the population very often did not give back more than 2s. per head. Liebig rated the agriculturists in his letter for paying twice the value for guano. He told them that they were being deluded by the chemists of the country, and were giving £13 a ton for what was worth only £6 or £7. For his own part he did not believe that the agriculturists of Great Britain were so foolish, and that they would not continue to give such a sum for any article if they did not find that they got a *quid pro quo*. In comparing sewage with other manures, it must be remembered that they could apply other manures when and how they pleased, but they had to take the sewage throughout the year and apply it every day. Sewage was an exceptional manure, and the only persons at all who used manure in a manner analogous to that in which sewage should be used were market gardeners, who, near London, sometimes applied 70 tons of manure per acre to their land, which quantity contained twice as much phosphoric acid and twice as much potash as 7,000 tons of sewage, and about two-thirds the quantity of ammonia. If, then, they looked upon market-gardening as the highest form of agriculture, they must allow that the application of 7,000 tons of sewage per acre could not be considered excessive. Baron Liebig stated in his letter that if a possibility was offered to the farmer to get back as sewage those matters which he had carried as food to the town, that was to say, if he gave his fields the same, both in quantity and in quality, which had been taken from them, their fertility might then be assured to an endless number of years, but was there a possibility of doing this? They had a plan before them by which it was proposed to apply the sewage of the three million of inhabitants of London to about 530,000 acres. If they applied this principle to the whole of England and Wales, the population being about 20,000,000, they would find that the whole amount of sewage would require about 3,500,000 acres of land, whereas the total acreage of England and Wales was about 37,000,000; and thus on the most extensive plan proposed only about a tithe of the whole of the land could receive the benefit of the sewage, and what was to become of the other nine-tenths? Baron Liebig stated that we were now refreshing our land and keep-

ing up our produce by the application of large importations of guano, which supply would very soon cease, and that our land would then go out of cultivation, and we should be reduced to a state of famine. This was a conclusion to which they might fairly come from Liebig's statement. But was there any such fear for English agriculturists? He believed not, for if the supply of guano should fail, he had no doubt they would exercise their ingenuity in discovering some other material which would answer the same purpose.

Mr. WM. HAWES said he quite agreed with the remarks of Mr. Alderman Mechi as to the great advance which this question had made, and he believed that there were plenty of gentlemen to be found in England who would take the matter into their consideration, and, after they had formed their opinions upon it, would support those opinions by their capital. In this way experiments would be made, and in the course of a few years he had no doubt that they would arrive at the solution of the problem, and would find out the best mode of applying sewage to the land. He did not believe that they would much longer neglect the great lesson which Providence had taught them, that of returning to the soil that which they had previously taken from it, and enabling it to reproduce the same materials. It was a question which required time, science, and capital. They must not disregard either of these, and if at any time, even during the present season, any new information could be obtained, or old information be supported by new arguments, the Society of Arts would be very glad to give an opportunity for re-opening the subject.

Mr. STUART BARKER, after expressing his satisfaction at hearing Mr. Morton's valuable paper, and alluding to the various schemes which had been proposed, said his own experience led him to the conclusion that the best means of applying sewage was by ordinary irrigation, and that by this method they could obtain a maximum result at a minimum of cost and labour. He had applied the sewage on a farm by means of a hose and tap, and scarcely any beneficial result had followed, but he afterwards cut an open drain and the result was immediately perceptible in the increased quality and crop of grass. If they were to commence the work again there was no doubt that some improvement might be made, but it must be recollected that the sewage of London was now at Barking, and that it could not be brought back, but must be dealt with under existing circumstances. If it was not allowed to go into the river as at present proposed, then it must be carried farther down the river. There was no reference in the paper to the application of sewage at Carlisle, where the experiment had been highly successful. A mode of deodorising the sewage, and applying it to the land had been adopted. The population was about 22,000, and the sewage was applied to 70 acres. During the last 30 years we had been violating the natural law, that what was taken from the earth should be returned to it again. Of late years, instead of putting the refuse of our towns on the land, we had thrown it away into the rivers, where it had been prejudicial in every respect. The connexion which necessarily existed between the application of sewage and the drainage of land, was most important. If sewage was to be applied in quantity, the land must be thoroughly drained in order to carry off the water, and unless this were done we should, by the frequent application of large quantities of sewage, convert our meadows and lowlands into so many marshes and bogs. But in many cases, where there was sufficient fall, and the pipes were large enough, the drains might be made to answer the two-fold purpose of draining the land and of conveying the sewage to any part of a field where it might be required. This might be accomplished by connecting the upper end of the drain (covered by a grate) with the carrier or feeder, and by means of plugs and spout drains, placed at intervals, the sewage might be thrown alternately over various portions of the land. The advantages

of this plan would be that sewage would be economised, and that the land at the lower end of the field would not receive the sewage which had already passed over the upper portion, and which had therefore lost much of its fertilising power, but would derive its supply fresh from the drains. We should not then see, as we frequently did now, a luxuriant crop at the upper end, and a deficient one in the lower part of the field, but the crop would be equally good throughout. In many positions, too, hydrants and hose and jet might thus be dispensed with, and the whole plan could be carried out by a small addition to the ordinary cost of drainage. This, he might say, was not a mere theory, but a plan which he had adopted in water meadows with success. He was glad to see that Lord Robert Montagu was again going to bring forward in Parliament the subject of the application of town sewage.

Dr. BACHOFFNER said that the appointment of another committee to inquire into this matter was the very last thing he should like to see, if it was to be such a committee as they had had before. The two schemes proposed reminded him of the opposing systems of homœopathy and allopathy, and his own experience led him to prefer the allopathic course of treatment—he preferred large doses of manure to small areas of land. As had been said, the sewage of London was already at Barking, and could not be kept there, but if the small dosing system were adopted, they would be obliged to deodorise it there, and turn it into the Thames. When they considered the millions of money which Londoners had spent to take the sewage to Barking, was it common sense to spend millions more to have it brought back again? In his opinion no system could be successful which did not use every atom of the sewage at such a distance from London that it should not be a nuisance to the metropolis. A great deal had been said about the value of London sewage, but the experiments which had been made by Dr. Hofmann and Mr. Witt had no value as regarded London sewage. The analyses were quite correct as far as they went, but they did not go far enough.

The CHAIRMAN said that, at that late period of the discussion, he should only enter into the subject to correct some grave misapprehensions. Mr. Walker had stated that the General Board of Health, or had implied that he (the Chairman) had at the outset recommended the application of a certain quantity of sewage—5,000 gallons per acre. He had made no recommendation of the sort. What he had done with the principle from the first had been to recommend trial works on every occasion for its application, both on account of the great diversity of soils (as noticed by Professor Voelcker), as well as of the various crops. Then, again, the kind of sewage, and the extent of its dilution, were matters of importance. In writings, and in this discussion, sewage manure had been assumed to be very much of one quality. In one town, however, the supply was at the rate of 300 gallons per house, the greater part of which was waste, (at Croydon, for example,) whilst in another on the constant system, the supply was not more than forty gallons per house. Then, again, no care had usually been taken as to the sort of soil-pan or water-closet introduced to ensure the least quantity of water being used for cleansing and conveyance, and consequently for dilution. In some, half a gallon of water sufficed, in others two gallons or more were used. Instructions had early been given to intercept sewage from old natural water-courses, and to prevent subsoil water, or surface water, getting into the sewers, sending the rainfall proper from the uncovered portions. In London, under a proper system of engineering, the old natural water-courses, the Old Bourne, the East Bourne, the West Bourne, would have been restored to their natural functions, and storm-waters would have been conveyed to the river through them; instead of which they had been treated as sewers, and made to discharge storm and subsoil water into most expensively and unnecessarily enlarged intercepting sewers. Hence the

condition of the sewage in the dry weather flow, in wet weather, and in storms, was widely varied. In one condition it would be valuable, in another so diluted as to be comparatively valueless. It had yet to be taught that internal care as to the adjustment of the apparatus for its collection and removal, was needful to preserve it in the best condition for its regular and efficient application. Again, by most chemists even, no distinction had been made of the wide difference between fresh and putrid sewage. Yet the difference was extreme. Professor Voelcker had proved, that throughout the country the farmers wasted full one-third of the farm yard manure by not using it fresh. The difference in efficiency between fresh and putrid sewage was even greater. The matter contained in the water discharged as sewage from London was generally a year old at least. It was the disintegrated matter, the overflow of cesspools, or of badly constructed drains of deposit, or sewers of deposit, of which there were some hundred miles in London, constantly giving off effluvia, wasting manure in houses and streets. People complained of the pollution of rivers; where putrid sewage from old town sewers was discharged into rivers it killed the fish; where fresh sewage was discharged it appeared to feed them. At Carlisle, which had been newly drained with pipe drains, it was stated that the fish greatly increased in quantity and improved in quality. At Ely, also, the anglers found their best sport at the mouth of the pipe sewers. So much for the consolation of those who were more anxious for the preservation of fish than for the population of towns. But there was a better use for sewage than feeding fish. In this diversity of the conditions of sewage he had always advised that all outlays should be preceded and governed by trial-works, to determine the extent of land that would absorb a given quantity in ordinary conditions. They should make the trials by the water-pot, or by the water-cart, in measured quantities, to see how much the land, with and without vegetation, would absorb and retain without letting any run off or run through at each dressing. Having thus ascertained the maximum quantity which the particular soil and vegetation would utilise, the next question to consider was, the most economical means of bringing the sewage to the land and distributing it. Iron pipes usually cost about £5 an acre. In some cases, where the ground had a natural inclination, as in Devonshire water meadows, they were laid out for less than that, but in general the water meadows cost much more to form; at Edinburgh they cost more than £16 an acre, and some of the Duke of Portland's water meadows, near Mansfield, cost as much as £100 an acre. In Lombardy, even, they often cost as much as £40 an acre; people had visited and looked at such places without inquiring either into the original outlay or the working expenses, and talked of the easy and natural flow of the water, without considering how much of it flowed away unapplied, which was commonly more than half. On some of the Edinburgh meadows the very rent of the space occupied by the sluices and carriers would, it had been declared, pay for the rent of the pipes and the expenses of distribution by steam power, by which, if properly conducted, as great an effect would be produced with one-third the quantity of sewage. If, however, those who had adopted steam and pipe distribution, whether for farm or town manures, had been guided, as they were generally advised, by previous trial works, they would have found that with high cultivation (which was the cheapest) one-half, or even one-third, of the pipeage or area of land would have sufficed. Trial works, well conducted and well observed, would settle the chief controversies raised. The persons to conduct such works should not be mere practical farmers; but the persons best qualified to work the land on such trials were market gardeners; and they should be guided in the application of the liquid manure by horticulturists who grew prize plants, who were accustomed

to the feeding of plants, and practically acquainted with the applications of liquefied manures, and who knew the right times and seasons for applying repeated doses to stimulate growth. In such hands far different results would be produced than those described in Mr. Morton's paper. When he was in Paris some time ago, he had the honour to speak to the Emperor on the subject, when he submitted that his Majesty's officers ought to conduct for themselves trial works for dealing with the sewage of Paris; they did so, and impartial persons would acknowledge that these trials were the best that had been made; they were conducted by Professor Moll, of the Conservatoire des Arts-et-Metiers, assisted by Mons. Mille, ingénieur-en-chef of Paris. These gentlemen, with others, came over to this country, and examined for themselves the chief works, at Watford, Leicester, and Rugby, the liquefied manure farms, and the Edinburgh irrigated meadows. They decided against the application of sewage by the method of submersion, and adopted in preference the method by steam and pipe distribution. Mr. Morton had written an English Encyclopædia of Agriculture, while Professor Moll, who occupied an analogous position in France, had written a French Encyclopædia on the same subject. He was, moreover, eminent as a practical agriculturist. He had conducted an experimental farm for the application of the sewage of Paris, and on this he had written a very able paper, embracing the whole subject of the application of the sewage of towns to agricultural production. Ill-health had obliged him to quit the farm, but he had recently written a letter, in which he had said that a practical experience for five years had made him more and more a partisan of his (the Chairman's) system of distribution, as the best means of applying the sewage manure of towns to land.

Mr. WALKER (of Rugby) wished to say a word or two in explanation. About 12 or 13 years ago, he and others had been led, by the report of the Commission, to believe that 5,000 gallons per acre was a fair quantity. This opinion was founded upon the reports of the various engineers who had inspected the works then existing in different parts of the country. The results varied from about 2,800 to 6,000, and, therefore, 5,000 was taken as being about a proper quantity.

The CHAIRMAN said it was now his pleasing duty to propose a vote of thanks to Mr. Morton for his valuable paper. He was sure they would all tender their thanks to him.

The vote of thanks having been passed,

Mr. MORTON acknowledged the compliment paid to him.

Mr. J. BAILEY DENTON writes:—As I had no opportunity, on Wednesday evening last, of saying a few words, and shall be absent on Wednesday next, I will ask you to insert the following remarks upon two points which I think have not received the attention that is due to them. In the first place, the full development of town sewage, as now practised, is dependent upon a copious supply of water, and a complete extension of the water-closet system, and, therefore, the supply of water to towns is a matter of the highest moment. It follows, upon this admission, that every town should not only look out for itself, to have a sufficient quantity of water, but that it should not dispose of its own sewage in such a way as to injuriously affect the water supply of other towns. Now, if we study the regime of our rivers, it will be seen that their flow depends upon the tributary influx of waters which are now being used, and will be used to a greater extent every day, by towns; and that if that use is to be converted into an abuse, by entire abstraction, if not by pollution, the question arises which of the two is the greater evil. To apply this question to the present discussion, we have only to suppose that the effect of irrigating land with sewage is to absorb the whole by vegetation and evaporation, which will certainly be the case if the

irrigation takes place between April and October. What, then, is to become of the rivers which lose this water? Depend upon it this is a great and important point, and that any mode of dealing with the sewage of towns which has not regard to the water economy of the country will not be a lasting one. In the case of tidal rivers, like the Thames at London, it may be out of place to refer to this, but we must remember that what is done in London will be taken as an example for all other towns; and that the water question in its several aspects is one inseparable from sewage. In the second place, I wish to draw the attention of the Society to the fact that great efforts, by highly scientific men, in France and Germany, are now being directed to such a modification of the water-closet system as shall separate the water, in a great measure, from the excrement, so as to allow the one to return, innocuous, to rivers, and the other to be arrested in such concentrated condition as to be really serviceable as manure. This separation is effected in the water-closets by having a pipe to receive such surplus water as is not required for lubricating the excrement-pipe, and conduct it away into the sewers, while the excrements themselves are conducted by another pipe into tanks, from whence, having been purchased, they are removed. M^rs. Moisselman, of Paris, has an ingenious plan of using quicklime so as to absorb the fluid excrements, and thus he converts the urine into solid without the loss of the ammonia. Though I cannot say that this mode of treatment is at present applicable to London, where a system of sewerage has been established inconsistent with any separation of the valuable part of the sewage from the bulk, yet I can well understand that the French plan is applicable to towns not yet sewered; and I know of no reason why householders should not withhold their sewage from the sewers if they can sell it; and thus the value of the bulk discharged by the sewers will be reduced. What, then, will become of these works which depend for their success on the value and utilization of the whole discharge of towns? I put these questions thus categorically because I feel that although the pollution of our rivers calls for immediate consideration, the abstraction of water never to return to the rivers is a matter of equal importance, and that any application of science which will allow of the return of the water into the rivers, after the valuable ingredients of sewage have been appropriated, is the object to which we ought to look, and not, in our hurry to get rid of a troublesome matter, take it for granted that science will never discover some means of adjusting the question to the requirements of all interests. To render my note apposite to the discussion, I should state, as immediately bearing upon the sewage of the metropolis, that some years back I investigated the Essex Marshes, and am enabled to state that at least 9-10ths of their extent must be under-drained before they can be profitably laid out for irrigation; and, I may add, as a fact capable of proof, that to irrigate the marshes of any low-lying valley is to increase its unhealthiness, though that may be greatly mitigated by under-drainage. I do not lay stress upon the increased evil of irrigating with sewage instead of water, as it must be manifest to everyone that miasma, which is due to the deleterious matter evolved with water under the influence of the atmosphere, is more likely to arise from the putrid matter of the London sewers than from the clearer waters which are generally used for irrigation. At this time I am engaged in superintending the conversion of water meadows in a well-known valley into dry meadows, because they are found unhealthy; and it seems the reverse of discretion to make the wet meadows in the metropolitan valley still more wet by irrigation, and apply sewage for the purpose, when the neighbourhood is already known to be subject to fever and ague.

Mr. WALKER, of Rugby, writes:—The great pressure for time last night prevented my replying to Dr. Gilbert, though I could only repeat, on the evidence of my own sight and that of all the neighbourhood, that the land

was treated in the way I had described—not in places here and there, but the whole of it—and systematically. Dr. Gilbert cannot deny that the sewage was running off one part almost unchanged, while other parts were thirsting for it, one part being flooded while another part was baked. He does not and cannot say that the waterings were regulated so as to follow immediately on the mowing. He does not and cannot say that the grass was not left lying in masses on the ground long after it was fit to cut, and when it was quite white at bottom. He cannot deny that the reason given for such delay in mowing was that the regulation cows kept to test the feeding and milk-giving quality of the grass were not ready for it. I went on the land time after time, and always found the same thing, and Mr. Campbell (employed to see to the measurements, &c.,) told me the days fixed for the various waterings. It is true these waterings could not always be given for want of material, but this only made bad worse. Mr. Morton did not describe the herbage as spoilt in isolated exceptional places, but generally; and if anyone entertains any doubt, the fields are only half-an-hour's walk from the Rugby station; and may be seen at any time, and they would carry the conviction that there is not the slightest foundation for Dr. Gilbert's assertion that it is only in exceptional places that the good herbage was destroyed.

Mr. JOHN BERNELL writes:—As this is a subject which I have for years studied as a manufacturing chemist and as a farmer (having farmed a large farm), I venture to send you my opinions. It is an established fact, that if you return to an acre of land the excreta of men or animals that have eaten the produce of that land, you will not only retain the land in its fertility, but you will increase this every year, because the land will absorb from the atmosphere some extra fertilizing properties beyond that furnished by the manure, so that under such circumstances it will increase in its fertility. This has been well proved in China and Belgium, where the most careful attention has been paid to the subject, so much so, that in Belgium, domestic servants on being hired reserve to themselves the power of selling their excreta, which was generally contracted for at £1 per annum, and of course it must be admitted that if the excreta of the inhabitants of London could be collected and applied to the land, as was done in Belgium, a large annual value would be derived thereby. Professor Liebig values it (I believe) at 6s. per head. But this is in my opinion surrounded with immense difficulties, when applied to London sewage. Chemists are too apt to look to the important facts above stated, without sufficiently considering the different circumstances under which London sewage is collected. The excreta of a human being, valued by its solid particles, does not exceed 1 lb. per day, and by the provision of our water supply to houses this is mixed with thirty gallons of water per head, or 800 lbs.; but this is not all, because you must add to this the washings of the streets, which will increase it to 400 or 500 lbs. of water to one lb. of excrement. Now we know, as chemists, that if this mixture remains for some days before it is distributed on the land, the animal matters putrefy, and give birth to ammonia and soluble phosphate, which are dissolved by the water, and held in suspension by it, so that all the manuring properties are in the water, and the solid contains none; and as we have only the ammonia and soluble phosphate generated from 1 lb. of excrement mixed with 400 lbs. of water, such solution will be so very weak, that unless it is applied in very large quantities it will be of little service to the land. And then you must consider that in doing this you must cover the land with an enormous amount of water, which in many cases may be detrimental. The beneficial results obtained by Alderman Mechi and others were realized under different circumstances. Their liquid sewage did not contain anything like the extra quantity of water which exists in London sewage

There is another great difficulty, which I think the Board of Works will find to be a most serious inconvenience to them, and a matter of enormous expense. They propose (I understand) to send the sewage to large tanks at Barking, where it is to remain until the solid particles subside, and then to run off the liquid into the Thames. Now this solid matter will be composed, chiefly, of the debris or small particles of stone, iron from horses' shoes, &c., all of which is utterly valueless as a manure; and it has been proved that no farmers will cart it away, even if it was given to them, as it is not worth the cost of cartage. But what will they do with it? It will soon amount to many thousands of tons; and if it is taken out of the tanks and heaped up it will still contain sufficient impurities to cause a very noxious vapour in the atmosphere, which may be seriously injurious to the health of the neighbourhood. I mentioned this in the Chemical Section of the last meeting of the British Association (1864), and the chemists present agreed with me in thinking that this was a most serious difficulty. If the liquid parts of the sewage of London were separated from the solid, and then by proper regulations, applied to certain descriptions of land, it would no doubt be very valuable, but then how are you to dispose of the sediment, or solid particles of stone, iron, &c. I do not think this has been sufficiently considered, but in my opinion it is most important to do so. Then as to the nature of the soil to which it should be applied. Professor Way showed us some years ago that if you filter water containing ammonia, &c., or putrid urine, through land containing a certain amount of clay, the clay absorbs all the ammonia and manuring property in the liquid, and then he stated that nature, by its wonderful chymical power, made from these compounds of clay and manuring properties a nourishing food for plants, but when the same liquid was filtered through sand, or earth not containing clay, the ammonia and manuring properties passed through the soil unchanged, and therefore no food for plants would be produced thereby in that soil. In the former case the putrid urine liquid was collected at the bottom of the filter as pure water, freed from all manuring or noxious smells, but in the latter it passed through nearly unchanged and as stinking as before. Presuming this to be correct, what would be the value of manuring the Maplin or any other sand with liquid sewage; and what profit would be derived by depositing on the sand particles of granite and iron from the London streets? None whatever. If they could mix with the Maplin Sand clay, and then apply liquid manure, a beneficial result would be obtained, but the cost of applying this clay would be great. The late Professor Buckland often stated that Woking Common could be rendered fertile by covering it with a stratum of clay, which he considered could be brought by rail and spread on the land at such a cost as would pay. If this was done, then London sewage distributed over it would be extremely beneficial. I make these remarks with the hope that gentlemen working on this subject will consider them, as, when the objections are correctly known, remedies may be suggested.

Proceedings of Institutions.

BIRMINGHAM AND MIDLAND INSTITUTE.—The programme for the winter term includes lectures on "The Socialistic Schemes of St. Simon and Fourier," by Dr. Hodgson; on "The Relations of Great Men to Women," by Mr. George Dawson, M.A.; on "The Life and Writings of Sydney Smith," by Mr. J. Bickerton Williams; on "The Re-production of Natural Forms by Art and Manufacture, having special reference to Art Metal Work in Birmingham," by Mr. B. Waterhouse Hawkin, F.L.S., F.G.S.; and "A Few Words on English Poets, with Selected Passages," by Lord Lyttelton.

Classes in many of the principal subjects included in the Society of Arts Examination will be regularly held. Penny lectures will also be delivered, the subjects being, "Optical Instruments," by Mr. C. J. Woodward; "Natural History," by Mr. B. Waterhouse Hawkins, F.L.S., F.G.S.; "The Human Body, its Functions, and How to keep it Healthy," by Dr. Alfred Hill; and "Colours, their Appearance in Nature and Production by Art," by Mr. Alfred S. Johnstone.

SHEFFIELD LITERARY AND PHILOSOPHICAL SOCIETY.—A conversazione was held in the Cutlers' Hall on Thursday, February 2nd, under the management of a committee, consisting of Messrs. Sorby, Baker, and Stuart. An interesting collection of objects, too numerous to particularise, was exhibited. It may, however, be mentioned that Mr. H. C. Sorby, F.R.S., of Sheffield, showed various spectra of fresh and old blood, illustrating a new method of detecting blood stains; stains of various kinds on linen, &c., as illustrations of the spectrum method in detecting minute quantities of blood when other methods would fail; and microscopical photographs of various kinds of iron and steel. Mr. Abel, Royal Arsenal, Woolwich, showed specimens of various fuzes for firing guns or for blasting by means of his ebonite exploder, for field use. Messrs. Day and Son, of Lincoln's-inn, showed a facsimile in photozincography of Shakspeare's first folio. Mr. Ellis, of Sheffield, showed specimens of a new method of photographic printing so as to make the contrast of light and shade not so objectionable, and some incised disks rotating by the influence of magnetism induced by the earth. The evening was enlivened by music.

WESTMINSTER WORKING MEN'S CLUB, DUCK-LANE.—The fourth anniversary of this Institution was held on Thursday evening, the 15th December, and passed off most successfully. The lecture-room was filled with working men. The chair was taken by Sir R. Carden, who was supported by the Rev. Canon Conway, the Rev. J. B. Owen, the Rev. T. Wright, J. G. Gent, Esq., Judge Payne, &c., and the committees of the Club and Temperance Association, and members of the singing class. Mrs. Cooper and Miss Adeline Cooper were also present. Mr. Edward Stephens, the secretary of the club, read the report, from which it appeared that the club was commenced, with one room, in December, 1860, an upper room being acquired and added in December, 1861; and in November, 1863, an adjoining house was taken, and the whole building remodelled to meet the requirements of the members, 1,040 of whom had been enrolled on the books; but as some had left the district, there were about 800 members, with an average weekly attendance of 240. The Institution was managed entirely by the members; the rules had been well observed, and not a book or periodical had been taken away. The educational classes had been of great benefit to the members, and they deeply regretted that Mr. Jewell, on account of increase of business, was compelled to cease his attendance; the Bible Class would shortly be resumed, and the members' thanks were offered to the Rev. Mr. Wright, who had so ably conducted it; thirteen lectures had been delivered on a variety of interesting and scientific subjects, many of them illustrated with diagrams, chemical experiments, &c. In the penny banks the deposits had been £81 4s. 1d., and from the commencement, in January, 1861, £232 1s. 9d., of which £215 1s. 3d. had been withdrawn. The enrolled Labour Loan Society had seventy-nine members, with a capital of £112 14s. 2½d. The loans granted during the year amounted to £228, in sums varying from 10s. to £13, and there had been in circulation, since the commencement of the society in July, 1861, £748 18s. 10d.; there had been no defaulters, only one summons having been taken out but never served. 259 temperance pledges had been taken, and £7 5s. had been paid into the sick fund (one penny per week); £5 11s. 3½d. had been paid in sickness, and there was a balance of £7 9s. 8½d. in

the treasurer's hands. The Barrow Club for costermongers had furnished fifteen members with barrows, who, at the expiration of fifty weeks, had become proprietors of their barrows, instead of going on all their lives paying 1s. 3d. or 1s. 6d. a-week for the hire of one. Allusion was made to the recent death of the club-room keeper, Mr. George Marchant, whom, as a mark of respect, the members had carried and followed to his last resting place in Brompton Cemetery; also to the expected loss of the club, through the improvements (so-called) which were causing the destruction of large numbers of their dwellings, forcing the members to crowd into the few poor houses left them, to the destruction of every moral and religious feeling, as they were excluded from the large model buildings erected on the site of their dwellings, either on account of their occupation or from the rent being beyond their means. The report concluded with the warm thanks of the committee and members to Miss Adeline Cooper, the foundress of the Institution, for her untiring care and zeal on their behalf, and to the many friends who had so kindly assisted them at all times. The Chairman (who was received with great applause) said he was glad he had called on Mr. Stephens to read the report first, as it really contained all that he could say about the excellence of the club. He could not realise the fact that so useful a building would be swept away, but certainly ample compensation ought to be made, so as to obtain an equally comfortable one. As regarded the dwellings of the poor, they had much cause for complaint, and he considered Mr. Peabody's money had not been properly employed, as the rents only suited those who had regular incomes of £1 15s. or £2 a-week; what the poor wanted was more dwellings with two rooms, one for the males and one for the females, at a rent of 2s. or 2s. 6d. a-week; when those were obtained we might be said to have made a step in the right direction. The Rev. Mr. Owen, Mr. Deputy-Judge Payne, and others addressed the meeting.

Fine Arts.

BUST OF MR. SASSOON.—Mr. Thomas Woolner has completed the clay model of a bust of the late Mr. David Sassoon, which is to be executed in marble for the Bombay Museum—an Institution which has largely shared in the munificence of a man who, if not widely known in this country, is famous throughout the extent of China and Japan, as well as India, Persia, and Turkey, for his exercise of charity and benevolence. To him is owing the endowment of a Reformatory and Industrial Institution at Bombay, a Public School for boys and girls, and a Synagogue at Bombay, as well as another at Poonah. The Sassoon Hospital at Poonah is one of the most costly and beneficent of his works. A Mechanics' Institute at Bombay, cemeteries there, as well as at Shanghai, Poonah, and Hong-Kong; a free poor-house at Poonah, together with substantial encouragements, in the form of almost unlimited contributions, to every benevolent and charitable undertaking on behalf of humanity, may be mentioned as some of the achievements of his life.

THE POURTALES GALLERY.—The coming dispersion of this famous collection is creating a great sensation in Paris. It is one of the most important private galleries in France, and indeed in the world, especially in antiquities, small bronzes, enamels, ivory carvings, medals, and miscellaneous articles; the pictures and sketches are not remarkably numerous, but they are very choice, and include some magnificent works. The late Count Pourtales Gorgier erected an elegant building for the reception of this fine museum in the Rue Tronchet, near the church of the Madeleine, and in this almost every article was to be seen in the most advantageous light. By will, he

directed that the collection should not be sold till ten years after his death, hoping, it is said, that the whole would be purchased by the French government and thus be kept together. This has not occurred, and in a few days the auctioneer will have to decide the destination of its remarkable and varied contents. The sale will occupy about thirty days, extending over the three coming months, and there is no doubt that the concourse of amateurs will be almost unprecedented. The gallery has been open to view four or five days; on the first three by ticket, and afterwards to the public at large, and the rooms have been literally crammed by the fashionable, the artistic, and the curious. How the gallery will be made to accommodate the amateurs, agents, and the public who will flock to it is a riddle. An unpleasant circumstance happened on the last day of the private exhibition; a cup and vase of exquisite Florentine bronze were stolen, and in spite of the doors being closed and strict search being made for suspicious characters, no clue was obtained to the culprit, who escaped with his booty.

FLANDRIN EXHIBITION.—It is decided that the collective exhibition of the works of the late Hippolyte Flandrin, which is to take place in the gallery of the Ecole des Beaux Arts, in Paris, shall be opened on the 15th of the present month, and closed on the same day in March.

MONUMENT TO MARSHAL MONCEY.—The monument which is about to be erected on the spot where the Barrière of Clichy formerly stood, to commemorate the brave defence made there in 1814, and which has already been referred to in the pages of the *Journal*, will be of a different kind to that first projected. It will resemble in some degree the beautiful fountain in the garden behind the great central market of Paris, in part originally designed and executed by the famous sculptor, Jean Gougon, who fell in the massacre of Saint Bartholomew, and also the tomb of Casimir Périer, in the cemetery of Père la Chaise. The statue of the marshal will be placed under an architectural canopy or *édicule*, with open arches on the four sides, and the events which the monument is intended to record will be represented in bas-reliefs on the base. This is certainly a great improvement on the proposed allegorical group of the marshal, surrounded by a soldier, a pensioner, a polytechnic scholar, and an *ouvrier*, supporting the genius of France, and is likely to prove a great ornament to the *Place* it is to decorate. Unfortunately, it is to be disfigured as a work of art by four lions' heads spouting water into as many basins below. The model, one-fifth the size of the intended monument, is now to be seen at the Hôtel de Ville.

Manufactures.

STEAM IN FRANCE.—The Government of France has just issued a decree materially altering the regulations laid down in 1843. These were not in accordance with the growth of machinery and trade, and very irksome to those against whom they operated. In 1850, there were but 6,832 steam engines in all France; in 1863 there were 22,516, representing a force of 617,890 horse-power, or nearly that of two millions of horses in reality, and which is set down as more than the force of all the men in the kingdom capable of labour. Under such circumstances, and the greatly extended practice and increased knowledge of engine-makers, the old regulations had become quite inapplicable. The new decree greatly simplifies the legislation on the subject. The testing of various parts of the machinery officially, till now imperative, has been done away with, except as regards the boiler, which will in future have to be proved up to twice the effective pressure of the steam. Steam engines are no longer to be regarded as dangerous machines, and may henceforth be set up without authority from the officers of government, and without any other form than a declaration of the fact. Boilers are, as heretofore, divided into

three classes, according to their capacity and the pressure to be employed; the regulations concerning the first class are greatly simplified, those of the second class may be set up in any factory or workshop not connected with the dwelling houses of other parties than the proprietor, his family, and workpeople, and the least dangerous class may be introduced even into houses occupied by any number of separate families; and even with regard to other cases, the consent of the neighbours is sufficient to set aside the regulations. Another important provision of the new law is, that all steam boilers shall consume their own smoke, six months grace being, however, allowed for the necessary arrangements to be made. There are other clauses well worth the attention of governments and sanitary boards.

AGRICULTURE IN FRANCE.—The condition of agriculture in France is undergoing the same changes as the trade and commerce of the country, and offers a wide field of study. A new green crop, called *Brome*, has recently attracted much attention, in consequence of the perseverance of M. A. Lavallée. A farmer at Trappes, M. Dailly, has produced 81 tons of green brome per hectare (or more than 12 tons per acre); M. Benoit, of Azy, obtained 35 kilogs. from 200 grammes of seed, or 185 times in weight of the seed; another farmer got 74 kilogs. from one kilogramme of seed. It is claimed for the brome that it promises to feed three bullocks where two were fed before; a magnificent prospect for the beef eater as well as the beef grower. The plant is well known in China, and the Minister of Agriculture, at the instance of M. Barral, the editor of the *Journal of Practical Agriculture*, has taken means for obtaining a good supply of the seed. One great peculiarity of the brome is its growth during an amount of cold which suspends all other vegetation, thus affording green food for cattle before and after all other sources are cut off, and fitting it peculiarly for exposed situations and arid soils. Some years since a farmer in the department of Finistère, received some leguminous seeds from America, and has ever since cultivated the plant with great success; this turns out now, it is said, to be identical with the brome in question. Two new varieties of trefoil are also being cultivated; one with white flowers, and being a month later than the other kinds; the other bearing yellow blossoms, and growing vigorously in silicious and almost sterile lands. A new lucerne from China, known there as *Mou-sou*, and described in M. Pauthier's elaborate work on the plants of the Celestial Empire, is also being experimented on, and is said to promise well. It is sown with millet, as lucerne is sown in Europe with oats and wheat, and will sprout even through snow. The leaves are yellowish, and its flowers, red and black, are so brilliant that the plant was at first used for garden borders. A Russian gentleman, M. Skatchkoff, has introduced the *Mou-sou* into the provinces of Odessa, Kasan, and Moscow, and, in spite of the cold, it has succeeded as well as in China.

Commerce.

COAL-TAR DYES.—The trade, which began in 1860, continues to expand, amounting probably at present to from a quarter to half-a-million annually. The colours are magenta, various shades of blue and violet, purple, yellow, orange, and green. The dyes are sent from London to Lancashire and Yorkshire, and various other places, to be used in the preparation of silk and cotton velvets, printed calicoes, delaines, merinos, finished cottons, silks, ribbons, flannels, and fancy and flannel shirtings. An export trade is beginning to China and the United States, the dyes being sent in their solid form to save freight. In consequence of the extensive use of the new article, the market for cochineal, safflower, and common dye woods has no doubt suffered very considerably.

COAL TRADE.—Messrs. W. H. Laird thus write in their Export Coal Circular:—In the year 1860 the Great Float, Birkenhead, was opened, and the Export Coal Trade was removed to that locality from the Morpeth and Egerton Docks, where, previous to that period, coal had been shipped. The arrangements for the trade have been improved; since it was first opened, three staiths, for the shipment of coal on the hydraulic principle, have been erected, and have gradually come into very general use for small-sized vessels, of 500 tons and under, but larger vessels, as a rule, still load by the barrow system. About September, 1863, the Great Low Water Basin was opened, which enabled vessels of the largest tonnage to enter the Float on any tide, either neap or spring; and when the sluicing operation is perfected, it is expected the basin will always be kept free of silt and accumulations of mud. The Great Northern deep water entrances into the Float from the river are expected to be completed in the course of a few months, and will render perfect, we hope, the facilities for ships entering or leaving this magnificent basin of water, and give still further impetus to its export trade in coal. We may give some idea of the progress of Birkenhead, by stating that the business done in coal there by rail in the year 1860 was 236,667 tons, in 1863 it was 427,931 tons, and in 1864 526,665 tons. During the past year Liverpool has made a stride in its coal export trade, not surpassed or equalled by any other port in the kingdom, and Birkenhead has contributed materially to this progress. On comparing statistics, we observe that the exports of 1863 as compared with 1862, from the separate localities, as classified, show:—From north-eastern ports a decrease of 7 per cent.; from Liverpool a decrease of 3½ per cent.; from Scotch a decrease of 3½ per cent.; from Yorkshire an increase of 4½ per cent.; from Severn an increase of 6½ per cent. The total of the exports 7,529,841, in 1863, against 7,694,558, in 1862, showing a decrease in 1863 of 2½ per cent. The year 1864, as compared with 1863, shows a material improvement in the coal trade of the country, more particularly as regards Liverpool and Birkenhead. The total exports from the port of Liverpool in 1864 were 746,842 tons, of which the shipments at Birkenhead have been 313,398, the increase of the port being nearly 80 per cent. as compared with 1863. The comparative statement of exports from each district during 1864 and 1863 is as follows:—From Yorkshire ports a decrease of 1 per cent.; from Northern ports an increase of 8 per cent.; from Liverpool ports an increase of 80 per cent.; from Severn ports an increase of 9 per cent.; from Scotch ports an increase of 11 per cent.; showing on the total exports of the kingdom an increase in 1864 of 544,964 tons, or about 6½ per cent., viz., 8,074,825 tons, against 7,529,841 tons in 1863.

SENEGAL COTTON.—The *Moniteur de la Flotte* contains an account of a successful plantation of 160 acres of cotton in Senegal. The ground was divided into five unequal parts. One portion, extending over 60 acres, was planted with the native cotton of Senegal. After the ground was cleared, well-handled drills were opened six feet apart, and the sowing was commenced at the beginning of August. In consequence of the abundant rain which fell that month, the young plants attained an unusual size. To the west and north of Taouey is a vast tract of land covered with brushwood, which grew to a great height. The ground was cleared with some difficulty, and sown, as an experiment, with seed of Georgian long-silk cotton, Jumel, Louisiana, and Algerian. The ground was selected because the various kinds of cotton could be planted near each other, and from its position it could be more easily inspected. The soil, moreover, is of various qualities—sandy and damp, suited to Algerian cotton, and in other places rich in vegetable matter. The planter began to clear the land on the 16th of August, he finished on the 6th of September, and the ground was levelled to the extent of 40 acres. On the 17th of September he opened trenches 1 foot wide and 8 inches deep. He sowed the seed of the long-silk Georgian cotton in the bottom of the

treach. In this he followed the Egyptian plan, because the long-stalk Georgian cotton requires irrigation. The trenches are calculated to retain the water and the consequent humidity as long as possible. The last sowing succeeded perfectly, and by the last accounts the young plants are flourishing. That was the second experiment the planter tried, and it extended over a surface of 24 acres. The planter expected that by the end of October the entire tract would be levelled and sown.

BEETROOT SUGAR.—Messrs. W. Connal and Co., of Glasgow, in their monthly circular, state—By the most recent statistics, the estimates of beetroot sugar, for the whole of Europe, for the season 1864-5, show an increase of from 35,000 to 40,000 tons over the ascertained production of 1863-64, which was 388,094 tons, as will be seen from the subjoined table. It is, however, obviously a crop more susceptible of injury from the weather than that produced from the cane in the tropics. The confident estimate formed in France of a crop for this season of 200,000 tons resulting, so far as the manufacture has progressed up to the latest date, in one not likely to exceed 128,000 tons, illustrates how critical it must prove as a source of supply. The manufacture, however, is followed out with great spirit; and whereas last year there were 364 manufactories at work, there is this year an increase of 33, notwithstanding that, as a branch of industry in France, it is considered to have been unremunerative last year to the cultivator as well as to the manufacturer:—

	1864-65. ESTIMATES.	1863-64. PRODUCTIONS.
Zollverein	165,000	155,180
France	120,000	108,467
Austria	65,000	60,916
Russia	40,000	35,000
Belgium	22,500	20,081
Poland and Sweden...	10,000	10,000
Holland.....	2,500	2,500
Spain	500	—
Total tons.....	425,500	388,094

With the view of securing a uniform system for duties and drawbacks, a treaty is now under the consideration of the Governments of England, France, Holland, and Belgium, but it is premature to offer an opinion until the scale is adjusted, as to its bearing on the interests of the British refiners.

THE PORCELAIN TRADE IN PARIS.—The gilding and painting of porcelain gives occupation, in Paris alone, to 1,872 hands, including 458 workwomen; the trade is carried on by 187 master-decorators, and produces to the amount of about 5,800,000*l.* a year, more than 860,000*l.* worth of which is exported. There are forty-three workmen who earn 8*l.* a day; five who earn 9*l.*, and four who earn 12*l.*; but these are the aristocracy of the trade, the generality earning only 5*l.* a day, when they are employed by a master. As for those who have the presumption of setting up for themselves and working on their own account, there are thirty-three who make less than 2,000*l.* profit a year, that is, who are actually starving; for their lodging, which must be fit to carry on the trade in, does not cost them less than 1,000*l.* a year; with the rest they and their family must live and find their clothing. Women generally earn from 2*l.* to 2*l.* 50*s.* a day; the most skilful earn 4*l.* 50*s.* at the utmost. The master decorator takes as many apprentices as he can, and it is they, who either get no wages at all or else not more than 25*s.* or 1*l.* a day, who do the largest share of the work. Females generally work at home, but their earnings rarely exceed 25*s.* or 30*s.* a fortnight.

Colonies.

NEW ZEALAND EXHIBITION.—The province of Canterbury is now rapidly preparing for the Exhibition. It has

the merit of possessing the first locomotive railway, and the illustrating of the works connected with that great engineering enterprise will form one of the most striking features in the Exhibition. It is proposed to exhibit, for instance, an immense section of the tunnel that is in the course of construction, with specimens of the rocks for every few feet that has been passed through. The geological strata and mineral resources of the province are to be fully illustrated by most elaborate maps, sections, and collections, both of scientific and economic interest. Maps and plans, showing the system of survey and land sales, proposed railway, road, and telegraphic routes, topographical features of the country, harbour improvements, architectural designs for public buildings are to be furnished, also specimens of lithography and engraving. The display of wools will show the important position occupied by the province in this respect, and enable the flock-owners to compare the produce from different parts of their own province with those of the rest of New Zealand. Works of art, articles of home manufacture, such as cabinet work, saddlery, &c., may also be looked for.

CLARENCE RIVER COTTON, NEW SOUTH WALES.—During the past season a proprietor planted four acres, two acres with New Orleans seed, and two with the Sea Island cotton, by way of experiment. The Sea Island was almost a failure, but from off the two acres of New Orleans 32*cwt.* of cotton in the seed was picked, which would yield about 1,000*lbs.* of clean cotton, and at the price obtained for the Clarence River cotton formerly sent home, namely, 2*s.* 2*d.* per *lb.*, would give a return at the rate of £57 18*s.* per acre. Six *cwt.* of the New Orleans cotton has been forwarded to Sydney to be ginned. The above yield, considering the very wet weather, shows that in ordinary seasons the crop would, in all probability, be much greater.

THE MELBOURNE AND SUBURBAN RAILWAY has been purchased, conditionally on legislative sanction, by the Hobson Bay Railway. The consideration for which the property is to be handed over is £267,000. In the construction of the line about £800,000 was expended, so that it is now sold for less than half its cost.

VICTORIAN RAILWAYS.—The traffic returns for the month of October show a total of receipts amounting to £44,710 6*s.* 7*d.* against £37,843 4*s.* 9*d.*, exhibiting an increase for the month of £6,866 1*s.* 10*d.*

Obituary.

DEATH OF THE PAINTER COURT.—France has lost an able artist by the death of Joseph Désiré Court. He was a pupil of Gros, and took the prize of Rome in 1821. His best known works are "The Death of Caesar," now in the Luxembourg, and the large picture of "Boissy d'Anglas," which forms part of the public collection of the town of Rouen, of which M. Court was curator. Some years since he was among the most fashionable, as well as ablest, portrait painters in Paris.

Publications Issued.

L'ECOLE. By Jules Simon. Lacroix and Co., Paris. 8*vo.*—An important volume by the author of some of the most remarkable works on social economy and cognate subjects that have appeared in France. M. Jules Simon was assistant minister of public instruction during the short reign of the republic of 1848, and earned a name in history by his indefatigable endeavours to raise the educational standard of the mass of his countrymen. He now represents one of the electoral divisions of Paris in the Chamber, and allows no opportunity of pursuing his former labours to escape him. M. Simon is the strenuous advocate of gratuitous and compulsory public education

greatest possible results were thus produced from the land so treated; but in the town of Leith, clear-headed, calculating Scotchmen were going to expend £66,000 in sewerage the Leith district; and in the face of a rental of £35 an acre on the opposite side of the city, they were spending this large amount of money to carry the pipes on to the sea that the sewage might there be discharged. If any one thought they were wrong in this, and would like to take the sewage and make use of it, he (Mr. Rawlinson) would be happy to place him in communication with the Corporation of Edinburgh, who would be only too happy to let him have the sewage for nothing. Surely there was something in this, in spite of what Alderman Mechi had said about the necessity of taking the sewage back to the land. Was there no escape from the dilemma otherwise than committing themselves to an extravagant expenditure of money which would not be remunerative? How long would a scheme of applying sewage be carried on if it did not pay? They might manage by some means or other to utilise the sewage in a profitable manner, but to say that the sewage of London, which was the produce of 3,000,000 of people, should be applied over 6,000,000 or even 1,000,000 acres, was an absolute fallacy. In his opinion no such system could be carried out. Then, again, with regard to the mode of applying sewage, he would give them in a rough way the amount which it would cost to pipe the whole area. In round numbers, the cast-iron pipes they would have to lay down would cost a shilling per inch in the diameter for a yard in length. If they took the greatest and most successful examples of irrigation of which they had any knowledge, where large volumes of water had long been regularly poured over the land, producing really great results, such as in the northern parts of Italy, and in some parts of India, they would find that the whole of the water was distributed by canals, open carriers, and open runnels. It might be said that this was water, and what they were now dealing with was sewage, but if they had attempted to distribute the water by underground conduits of cast-iron, the works would have cost 24 times as much as they had done. Lord Robert Montagu had accused him of having given evidence before the Committee which was contrary to his opinions. He could only say that if in giving his evidence he failed to make his meaning clear it was from no dishonest motive; but his own belief was that his evidence and his opinions were in perfect accordance.

Mr. Bowring said he should be glad to accept Mr. Rawlinson's offer to be put in communication with the authorities at Leith, and would gladly take the sewage of that place. As they had heard so often, there were two modes of applying the sewage which were now being advocated by opposing parties, one that of small dressings over large areas, and the other large dressings over small areas. The mode, however, to be adopted was that which would enable the real value of the sewage to be fully made use of, giving the ratepayer his share in this value. For his own part, he believed the sewage was a very valuable property. Baron Liebig and others said that the sewage was worth about twopence per ton. Hofmann and Witt had adopted one method of proceeding, and Baron Liebig another, and yet they all three arrived at about the same result as to the actual value of the sewage. If the sewage were applied in such enormous dressings as 10,000 to 20,000 tons to an acre, as done at Edinburgh, and as proposed by Messrs. Napier and Hope, how was it possible to recover one-fiftieth part of its value? Liebig gave it as his opinion that sand was the last soil and grass the last crop to which sewage should be applied. He did not believe that the Board of Works had had the interest of the ratepayers of the metropolis at heart in what they had done, and it would be a source of satisfaction to everybody if that body would only come forward and allow their plans to be tested. All interested in the matter must be glad that Lord Robert Montagu had again taken the subject up, and that there would be an inquiry into

all the plans which had been proposed for the utilisation of the sewage, entirely without the assistance of the Metropolitan Board of Works.

Mr. HARRIS said there was one point which they seemed to have lost sight of, and that was that the Metropolitan Board of Works required the sewage to be taken away so as not to be a nuisance. Taking the sewage of the northern part of the metropolis at the quantity stated, it would be found that if it travelled at the rate of a mile and a half an hour, it would occupy a channel of something like 20 feet wide and 6 feet deep. Here was a small river constantly coming down to be provided for, and which must be dealt with as it came. This was a fact which materially affected the whole question. He would say nothing about the engineering part of the case, but the chemical question was a very important one. It was now generally acknowledged by chemists that the sewage was worth about 6s. per head of the population. It was best to speak of it as so much per head, because if the value per ton were given, the question of dilution entered so materially into the matter that it was impossible to get at anything like correct results. The sewage of Croydon, for instance, was diluted to twice the extent of that of Watford, and of course the intrinsic value of a ton in one case would be double that which it would be in the other. But what did Liebig say in his letter about the sewage in this diluted state? He said, "In the diluted state in which these elements are present in sewer water they are without any manurial value." The ratepayers of London were the owners of this stuff in its rough state, and the farmers were the manufacturers who had to get the metal from the ore supplied to them by the ratepayers. As far as experience went, he found sewage so far from returning 6s. per head of the population very often did not give back more than 2s. per head. Liebig rated the agriculturists in his letter for paying twice the value for guano. He told them that they were being deluded by the chemists of the country, and were giving £13 a ton for what was worth only £6 or £7. For his own part he did not believe that the agriculturists of Great Britain were so foolish, and that they would not continue to give such a sum for any article if they did not find that they got a *quid pro quo*. In comparing sewage with other manures, it must be remembered that they could apply other manures when and how they pleased, but they had to take the sewage throughout the year and apply it every day. Sewage was an exceptional manure, and the only persons at all who used manure in a manner analogous to that in which sewage should be used were market gardeners, who, near London, sometimes applied 70 tons of manure per acre to their land, which quantity contained twice as much phosphoric acid and twice as much potash as 7,000 tons of sewage, and about two-thirds the quantity of ammonia. If, then, they looked upon market-gardening as the highest form of agriculture, they must allow that the application of 7,000 tons of sewage per acre could not be considered excessive. Baron Liebig stated in his letter that if a possibility was offered to the farmer to get back as sewage these matters which he had carried as food to the town, that was to say, if he gave his fields the same, both in quantity and in quality, which had been taken from them, their fertility might then be assured to an endless number of years, but was there a possibility of doing this? They had a plan before them by which it was proposed to apply the sewage of the three million of inhabitants of London to about 530,000 acres. If they applied this principle to the whole of England and Wales, the population being about 20,000,000, they would find that the whole amount of sewage would require about 3,500,000 acres of land, whereas the total acreage of England and Wales was about 37,000,000; and thus on the most extensive plan proposed only about a tithe of the whole of the land could receive the benefit of the sewage, and what was to become of the other nine-tenths? Baron Liebig stated that we were now refreshing our land and keep-

ing up our produce by the application of large importations of guano, which supply would very soon cease, and that our land would then go out of cultivation, and we should be reduced to a state of famine. This was a conclusion to which they might fairly come from Liebig's statement. But was there any such fear for English agriculturists? He believed not, for if the supply of guano should fail, he had no doubt they would exercise their ingenuity in discovering some other material which would answer the same purpose.

Mr. Wm. HAWES said he quite agreed with the remarks of Mr. Alderman Meohl as to the great advance which this question had made, and he believed that there were plenty of gentlemen to be found in England who would take the matter into their consideration, and, after they had formed their opinions upon it, would support those opinions by their capital. In this way experiments would be made, and in the course of a few years he had no doubt that they would arrive at the solution of the problem, and would find out the best mode of applying sewage to the land. He did not believe that they would much longer neglect the great lesson which Providence had taught them, that of returning to the soil that which they had previously taken from it, and enabling it to reproduce the same materials. It was a question which required time, science, and capital. They must not disregard either of these, and if at any time, even during the present session, any new information could be obtained, or old information be supported by new arguments, the Society of Arts would be very glad to give an opportunity for re-opening the subject.

Mr. STUART BARKER, after expressing his satisfaction at hearing Mr. Morton's valuable paper, and alluding to the various schemes which had been proposed, said his own experience led him to the conclusion that the best means of applying sewage was by ordinary irrigation, and that by this method they could obtain a maximum result at a minimum of cost and labour. He had applied the sewage on a farm by means of a hose and tap, and scarcely any beneficial result had followed, but he afterwards cut an open drain and the result was immediately perceptible in the increased quality and crop of grass. If they were to commence the work again there was no doubt that some improvement might be made, but it must be recollected that the sewage of London was now at Barking, and that it could not be brought back, but must be dealt with under existing circumstances. If it was not allowed to go into the river as at present proposed, then it must be carried farther down the river. There was no reference in the paper to the application of sewage at Carlisle, where the experiment had been highly successful. A mode of deodorising the sewage, and applying it to the land had been adopted. The population was about 22,000, and the sewage was applied to 70 acres. During the last 30 years we had been violating the natural law, that what was taken from the earth should be returned to it again. Of late years, instead of putting the refuse of our towns on the land, we had thrown it away into the rivers, where it had been prejudicial in every respect. The connexion which necessarily existed between the application of sewage and the drainage of land, was most important. If sewage was to be applied in quantity, the land must be thoroughly drained in order to carry off the water, and unless this were done we should, by the frequent application of large quantities of sewage, convert our meadows and lowlands into so many marshes and bogs. But in many cases, where there was sufficient fall, and the pipes were large enough, the drains might be made to answer the two-fold purpose of draining the land and of conveying the sewage to any part of a field where it might be required. This might be accomplished by connecting the upper end of the drain (covered by a grate) with the carrier or feeder, and by means of plugs and spout drains, placed at intervals, the sewage might be thrown alternately over various portions of the land. The advantages

of this plan would be that sewage would be economised, and that the land at the lower end of the field would not receive the sewage which had already passed over the upper portion, and which had therefore lost much of its fertilising power, but would derive its supply fresh from the drains. We should not then see, as we frequently did now, a luxuriant crop at the upper end, and a deficient one in the lower part of the field, but the crop would be equally good throughout. In many positions, too, hydrants and hose and jet might thus be dispensed with, and the whole plan could be carried out by a small addition to the ordinary cost of drainage. This, he might say, was not a mere theory, but a plan which he had adopted in water meadows with success. He was glad to see that Lord Robert Montagu was again going to bring forward in Parliament the subject of the application of town sewage.

Dr. BACHOFFNER said that the appointment of another committee to inquire into this matter was the very last thing he should like to see, if it was to be such a committee as they had had before. The two schemes proposed reminded him of the opposing systems of homeopathy and allopathy, and his own experience led him to prefer the allopathic course of treatment—he preferred large doses of manure to small areas of land. As had been said, the sewage of London was already at Barking, and could not be kept there, but if the small dosing system were adopted, they would be obliged to deodorise it there, and turn it into the Thames. When they considered the millions of money which Londoners had spent to take the sewage to Barking, was it common sense to spend millions more to have it brought back again? In his opinion no system could be successful which did not use every atom of the sewage at such a distance from London that it should not be a nuisance to the metropolis. A great deal had been said about the value of London sewage, but the experiments which had been made by Dr. Hofmann and Mr. Witt had no value as regarded London sewage. The analyses were quite correct as far as they went, but they did not go far enough.

The CHAIRMAN said that, at that late period of the discussion, he should only enter into the subject to correct some grave misapprehensions. Mr. Walker had stated that the General Board of Health, or had implied that he (the Chairman) had at the outset recommended the application of a certain quantity of sewage—5,000 gallons per acre. He had made no recommendation of the sort. What he had done with the principle from the first had been to recommend trial works on every occasion for its application, both on account of the great diversity of soils (as noticed by Professor Voelcker), as well as of the various crops. Then, again, the kind of sewage, and the extent of its dilution, were matters of importance. In writings, and in this discussion, sewage manure had been assumed to be very much of one quality. In one town, however, the supply was at the rate of 300 gallons per house, the greater part of which was waste, (at Croydon, for example,) whilst in another on the constant system, the supply was not more than forty gallons per house. Then, again, no care had usually been taken as to the sort of soil-pan or water-closet introduced to ensure the least quantity of water being used for cleansing and conveyance, and consequently for dilution. In some, half a gallon of water sufficed, in others two gallons or more were used. Instructions had early been given to intercept sewage from old natural water-courses, and to prevent subsoil water, or surface water, getting into the sewers, sending the rainfall proper from the uncovered portions. In London, under a proper system of engineering, the old natural water-courses, the Old Bourn, the East Bourn, the West Bourn, would have been restored to their natural functions, and storm-waters would have been conveyed to the river through them; instead of which they had been treated as sewers, and made to discharge storm and subsoil water into most expensively and unnecessarily enlarged intercepting sewers. Hence the

glass; the walls are composed, like those of the old palace, of alternate courses of brick and stone, and the roof is covered with tiles cut in geometric forms. The intended application of this structure is the formation of a collection of Italian carriages of the sixteenth century, and probably others. There are three curious vehicles now in the adjoining museum which will form part of the new department.

GEOLOGISTS' ASSOCIATION.—On Tuesday evening, at the ordinary meeting, Mr. S. Carter Blake, F.G.S., read a paper on the "Geological Evidences of the present Domesticated Animals;" and Mr. Wm. Hislop, F.R.A.S., read his third note on "Microscopic Geology." The meeting was well attended, and some interesting remarks were elicited by the discussion which followed the reading of the papers.

MEETINGS FOR THE ENSUING WEEK.

- MON.**...Society of Arts, 8. Cantor Lectures. Professor Ansted, F.R.S., "On the Applications of Geology to the Arts and Manufactures."
B. Geographical, 8½. 1. Mr. R. Temple, "On the Basin of the River Mahanuddy." 2. Dr. Bastian, "Visit to the Ruined Cities of Cambodia."
- TUES.**...Royal Inst., 3. Prof. Tyndall, F.R.S., "On Electricity." Medical and Chirurgical, 8½. Civil Engineers, 8. Mr. John England, "Giffard's Injector." Zoological, 8½. Syro-Egyptian, 7½. Rev. John Mills, "On the Church of the Holy Sepulchre." Anthropological, 8.
- WED.**...Society of Arts, 8. Mr. Thomas Webster, Q.C., F.R.S., "On the Claims of Authors and Inventors to Property in and Protection for Designs and Inventions first published at Industrial Exhibitions." Meteorological, 7. London Inst., 7. R. Society of Literature, 4½.

Patents.

From Commissioners of Patents Journal, February 3rd.

GRANTS OF PROVISIONAL PROTECTION.

- Books, &c., preserving from fire—71—F. Wiese.
Boots, &c., manufacture of—169—W. Clark.
Bottles, closing the mouths of—132—H. J. Rogers and J. M. Scholfield.
Burners and glasses, petroleum and coal oil—201—M. A. Dietz.
Clasps, &c.—188—A. I. L. Gordon.
Combs, elastic dents of expanding and contracting—189—M. Robinson.
Cooking—150—S. Ballard.
Cotton, machinery for ginning—44—B. Dobson, W. Slater and R. Halliwell.
Crinoline skirts, manufacture of—108—J. Knight.
Curtains, suspension of—193—J. Badcock.
Driving rolls for rolling metals—135—R. A. Brooman.
Elastic mattresses and bedding—99—E. T. Hughes.
Engines, packings of pistons and piston rods of—155—W. R. Foster.
Fibrous materials, ginning and cleaning—191—C. B. W. Hoepli and W. Gunther.
Fibrous substances, machinery for preparing, &c.—130—J. B. Farrar and J. Hirst.
Fire-arms, breech-loading—106—G. H. Daw.
Fire-arms, breech-loading—138—G. T. Bondfield.
Fire-arms, breech-loading—139—J. S. Edge, sen.
Fire-arms, breech-loading—152—W. E. Newton.
Floor cloths, manufacture of—197—J. B. Wood.
Flower box, ornamental—126—G. Colven.
Fluids, presses for the expression of—134—J. Marshall.

- Fluids, regulating the supply of—2659—N. N. L. Lonsdale.
Fog and storm signals, &c.—126—T. Bourne.
Folding chairs, &c.—199—T. Brown.
Furnaces—103—M. Henry.
Furnaces—110—W. S. Longbridge and J. Maah.
Gas retorts, apparatus for charging and drawing—142—S. J. Best and J. J. Holden.
Grain, cleaning and decorticating—115—W. Ager.
Grain, mills for grinding and pulverizing—211—A. Stevenson.
Hammers and pile drivers—181—W. E. Newton.
Iron and steel, furnaces used in the manufacture of—173—J. Hewes.
Keys and locks, construction of—92—J. F. Heather.
Liquid manure, apparatus for distributing—100—W. Russ.
Liquids, ascertaining and indicating the strength of—122—R. A. Brooman.
Looms, &c.—153—J. Burch.
Metals, furnaces for smelting—209—W. R. J. & A. Woodward, jun.
Metals, shaping and forging—165—J. A. Shipton and R. Mitchell.
Mules for planing and doubling—133—W. Rowbottom.
Music, teaching and transposing—102—R. A. Brooman.
Ordnance and gun barrels—213—J. Marshall and H. Mills.
Ordnance, breech-loading—2994—F. A. Willson.
Phosphates of lime, &c., for agricultural uses—140—R. A. Brooman.
Pianofortes—141—F. H. Lakin.
Projectiles—171—G. A. Clark.
Railway carriages, signal between passengers and guards—107—J. B. Hill.
Railways, communication between passengers and guards—97—I. Goodlad.
Railways, waggons for the conveyance of cattle upon—3174—W. Reid.
Railways, working switches and signals of—147—W. Jeffreys.
Railway trains, communication between passengers and guards of—121—R. Lea.
Railway trains, communication between passengers, guard, &c.—179—W. Mather.
Railway trains, taking up and delivering mails, &c., while in motion—177—W. Clark.
Railway trains, transmitting letter bags and parcels to and from while in motion—187—C. D. Abel.
Roads, construction and paving of—116—T. G. Pagano.
Sails, reeling and furling—148—A. B. Bull.
Sewing machines—13—G. Mascart.
Sewing machines—144—C. T. Jenkins.
Sewing machine shuttles—163—J. F. Bradbury.
Ship building—137—J. Bettelley.
Ship compasses—128—J. Lilley.
Ships, giving buoyancy to, and the propulsion of—2405—J. Vine.
Shirt fronts, securing studs in—175—C. Searle.
Sleeve links—120—W. H. Richards.
Soda and potash, manufacture of—2876—A. G. Hunter.
Steam boilers—113—R. Lewis.
Steam boilers, preventing incrustation in—119—G. Davies.
Steam engines—111—W. Brookes.
Steam engines—167—T. C. Durham.
Steam engines—183—T. Lester.
Stones, smoothing the surface of—154—J. Coulter and H. Harpin.
Telegraph conductors and cables, coverings for—98—J. Fuller.
Theatres, working all stage scenery in—131—W. Edwin.
Tills—104—G. Gaze.
Tobacco, machinery for pressing and cutting—123—A. V. Newton.
Transmitting and converting reciprocating motion into rotary motion—145—W. J. Cunningham.
Tubes, cast steel and other metallic—3251—W. H. Brown.
Umbrellas, &c.—114—J. Weekes.
Vehicles, registering the distance travelled by—91—C. M. Bathias.
Warp machinery, manufacture of looped fabrics in—117—W. Wilkins.
Watches, construction of—157—C. D. Abel.
Window-blind cord check—195—E. Templemore.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

FEB. 22.—"On the Municipal Organisation of Paris, especially with reference to Public Works." By GEORGE R. BURNELL, Esq., F.G.S.

MARCH 1.—"On the Means employed in taking Fish, especially with reference to Submarine Illumination." By F. W. CAMPIN, Esq.

CANTOR LECTURES.

The Second Course of Cantor Lectures, the subject being "The Applications of Geology to the Arts and Manufactures," by Professor D. T. ANSTED, M.A., F.R.S., is now being delivered on Monday evenings, at Eight o'clock, as follows :—

FEB. 20TH.—LECTURE 3.—On Mineral Materials used for the Purposes of Construction: Plastic and Incoherent Materials (Clays and Sands).

FEB. 27TH.—LECTURE 4.—On Mineral Materials (continued): Building Stones and Slates, and their Relative Value under given Circumstances of Exposure, and on Methods of Quarrying.

MARCH 6TH.—LECTURE 5.—On Stratified Deposits of Minerals, as Coal and Iron Ore, usually obtained by Mining Operations, and on Mining Methods for such Deposits.

MARCH 13TH.—LECTURE 6.—On Metalliferous Veins or Lodes and their Contents, and on the Extraction of Metalliferous Minerals from Lodes.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

FINAL EXAMINATIONS—BOTANY.

In addition to the Prizes in this subject offered by the Society of Arts to candidates taking a Certificate of the First Class, the Royal Horticultural Society offers five prizes, of £5, £4, £3, £2, and £1 respectively, to the five candi-

dates, being gardeners by profession, who, taking any grade of certificate in Botany, obtain the highest number of marks in that subject at the Final Examinations in April, 1865.

MUSICAL EDUCATION.

The Council have appointed a Committee to inquire into the present state of Musical Education at home and abroad.

A letter has been addressed to the Foreign Office, requesting the aid of Earl Russell in obtaining for the use of the Committee, through the intervention of Her Majesty's Ministers abroad, detailed information concerning the Musical Schools in the principal capitals of Europe, and to this letter the following reply has been received :—

Foreign Office, Feb. 6th, 1865.

SIR,—I have laid before Earl Russell your letter of the 27th ultimo, respecting the desire of the Council of the Society of Arts to obtain, through the intervention of Her Majesty's Representatives at certain places abroad, information with reference to Musical Schools at the places indicated, and I am to request that you will inform the Council that instructions have been sent accordingly.

I am, Sir,

Your most obedient humble servant,

J. HAMMOND.

The Committee issued the following queries to the professors, amateurs, and others interested in the subject, and desire to obtain their opinions thereon. Members willing to aid them in this inquiry are requested to communicate their views :—

1. What are the essential differences between the plan of the Royal Academy of Music in London, and the Conservatoires of the Continent, with regard to—

a. Their constitution and management;

b. Their revenues as derived from the State, annual subscriptions, fees from pupils, concerts, or other sources.

2. State the nature of any other Institution in the metropolis or the provinces, for providing or improving Musical Education.

3. The expediency or otherwise of taking the present Royal Academy of Music as the basis of any enlarged Institution in this country.

4. What improvements might be effected in the Royal Academy of Music?

5. Is any union between the Royal Academy and similar Schools, Cathedral Choirs, or Local Institutions desirable or otherwise?

6. Could the Local Examinations of the Royal Academy of Music be extended, and how?

7. Does the Royal Academy in any way promote the improvement of Military Music?

8. Could any useful connection be established by the Academy with the Regimental Volunteers or other trained Musical Bands?

9. What proper security may be taken for obtaining due results from any Funds granted by Parliament to the Royal Academy?

10. What is your opinion respecting—

- a. The advantages derivable from Public Concerts.
- b. The test of Musical Proficiency by Examinations.
- c. The Formation of a National Musical Library, and of a Collection of Musical Instruments, by gifts, loans, &c.
- d. The Competitive trials of Performers and of Musical Instruments.
- e. The use of a standing Musical Jury, as in the French Institute.

Proceedings of the Society.

CANTOR LECTURES.

SECOND COURSE.—SECOND LECTURE.—MONDAY, FEB. 13.
SPRINGS AND WATER SUPPLY.

Professor ANSTED remarked that a supply of fresh water is a matter of such extreme importance that every inquiry connected with it is well worthy of attention. It is connected with geology, for the conditions under which water exists in the earth depend on the arrangement of rocks and the facilities for circulation among and between them. He proposed to point out the great facts on which water-circulation and water-supply depend, and enable his audience to understand and appreciate the efforts made to obtain ample supplies when required. The source of water is the ocean; the means by which it is transferred from the ocean to the land is the atmosphere; and the circulation of water through the earth is the fact to be borne in mind in all investigations concerning water. Of the rain that falls a large proportion is attracted to the summits and flanks of mountain-chains, to upland valleys and lofty plains; the spots of heaviest rain-fall have the sea at no great distance, and winds blowing more frequently from the sea than from the interior of the country. Much rain reaches the earth on slopes looking towards the sea, and a large quantity of water is conducted by natural channels to rivers, and across low lands to the ocean. But of a large district only a small proportion consists of river-courses, whilst the rain falls on the whole surface. The soil becomes wet, the subsoil behaves in like manner, and moisture reaches the underlying rock. Of the rocks some are sands, sandstones, or limestones, and others fragmentary rocks. These allow water to enter, and give back the water at need. Others are impermeable strata, between or amongst which are beds shutting off water. Such are clays. All rocks contain water. Granites and compact marbles, in their driest state, hold from $\frac{1}{4}$ to $\frac{1}{2}$ per cent. by weight; and, as a cubic yard of such stone weighs two tons, each ton of the least absorbent rock will contain a pint of water. The water held by common loose sea-sand amounts to at

least two gallons in a cubic foot. In ordinary sandstones nearly half that quantity can be contained; and in best sandstones five pints of water are contained in each cubic foot. Thus in an area of such sandstone, occupying ten square miles, and ten yards in thickness, the quantity of water contained is from four to five hundred millions of gallons. This would fill a reservoir of a hundred acres to the depth of ten feet. But sandstones are rarely without bands of clay separating their water contents into sheets, and owing to faults and vertical bands of compact mineral, a sandstone district is broken up into boxes, each one of which is independent to some extent of the rest. Sandstones have also been tilted, and stand at a considerable pitch, tolerably uniform over great distances. Some varieties of sand-rock passing into pudding-stone on the one hand and quartzite on the other contain no water, but even in such rocks there are fissures and cracks wherever there is an exposed surface. Into these water penetrates. Of limestones the least absorbent hold four pints in the cubic foot; while a cubic foot of Bath stone will absorb a gallon; and some magnesian limestones twelve pints. A cubic foot of soft chalk will hold two gallons of water, or as much as loose sand, taking up half its own bulk of water and yet hardly appearing wet. By pumping, a large quantity of water may be obtained from chalk, for it acts as a sponge, the water sinking to the bottom. In most limestones the water does not come away by pumping, being kept back by friction as well as by capillary attraction. Limestone is more available as a water-bearing rock than sandstone, being more cracked and fissured at all depths. It is acted on by water, both mechanically by wear, and chemically by becoming dissolved. The cavernous nature of limestone is one of its most remarkable features, and at the intervals of strata there are spaces allowing a free passage to water, besides vertical fissures, dividing up the mass into smaller areas, each one of which has its own water system, though all communicate. Clays often contain as much as ten per cent. of water (by weight), and clay rocks, such as the varieties of schist, which are extremely numerous, are similarly constituted. Water is present in great abundance in the rocks near the surface of the earth, not only in the substance of all, but in the interstices. Of the rain that falls upon the earth at any place not more than one-third runs off the surface and enters the sea by rivers. What becomes of the rest? Part is evaporated; part supplies life; but an ample supply enters the earth. Down natural channels the water passes; occasionally through a permeable rock, sometimes slowly with much interference, and sometimes into cavities. It is conveyed horizontally, and rises here and there to the surface under the influence of the pressure of a column whose height has reference to the level of the spot at which it first entered as rain. This circulation is due to the natural inequalities of the land. As the rain falls mostly on mountains and high ground, and rocks are usually tilted towards the plains, the tendency of water to run down a slope in the interior of the earth as well as on its surface, ensures the conveyance of ample supplies. These may exist under pressure arising from the fact that the channels formed between two impermeable rocks are closed pipes. But because the dip is not always the same as the natural slope of the surface, and that faults remove rocks to a considerable distance vertically, water will sometimes find an issue at a considerable distance; it may well up at a fault, or come out at an artificial cutting, though always at a lower level than that at which it entered. Water obtained by any of these means is called a spring. Land springs occur in sand or gravel, resting on impermeable strata, and receiving a larger quantity of rain on their surface than is carried off by evaporation or streams. The water accumulates below, instead of upon the surface. Its depth is rarely great, and it is reached by wells. The supply varies with the rain-fall, and in dry seasons fails or gets much lower than usual. The quality of such water is

liable to injury, owing to the filtration into it of organic matter from above. Wells in such localities sometimes yield upwards of a hundred gallons of solid matter to the gallon. A second class of natural springs issue on hill sides, in valleys, or on plains surrounded by higher land. They depend on the outcrop of strata which carry water, but rest on other strata that are impermeable. The issuing of springs under these circumstances is easily understood; though the phenomena may become complicated and obscure. The source of the supply may be distant, and much above the level of the point of emergence. When it issues, the water may be a considerable stream, or may drain out in a multitude of springs on a continuous line of outcrop. Groups of springs of this kind are often important, dividing the irregularities of season over a considerable time, and to some extent independent of season. The water, having filtered through the earth for a long distance, is fresh and wholesome. Springs of this kind may be tapped on their way to the natural outlet. The supply they bring is limited, and what is taken at any one place is taken from the general stock. It may be that the upper rock is porous and rests on an underlying, impermeable stratum. The supply is then more abundant but less regular. Good examples of such springs exist in the Cotswolds, where, all along the oolites with the lias, groups of springs issue. A few days after the rain most of these springs become swollen, and run freely. After dry summer weather the supply falls off. In this case the dip of the beds changes, but the main cause of the irregularity must be sought for in the fact that, though crop-springs in one sense, they are land-springs in the nature of their supply. A third class of mineral springs issues where the containing rocks are interrupted by faults. In this case there are several possibilities. A fault acting as a wall, because it is filled with clay, will in most cases be accompanied by a spring, though not always at the exact spot where we might be inclined to look for it. Artesian springs occur in many places, and have been obtained artificially from the earliest times. A permeable bed between two impermeable beds, crops out at the surface, and there receives the rain-fall and surface-water. The level of this outcrop is higher than that of a part of the surrounding country beneath which the strata pass, owing to their dip. The permeable bed thus represents a bent tube, and may be kept full of water under a pressure corresponding to the height at which the porous bed crops out. If, then, a well is sunk or a hole bored, the water will rise in it, not only towards, but even in some cases far above, the surface, in a jet. The chief Artesian wells, and the oldest in Europe, are in the north of France, and they seem to have spread thence through the other countries of Europe. They are sunk through the lower tertiary strata to the chalk, from whose upper beds the water is generally derived. The construction of this class of wells is easy and inexpensive. The Artesian wells of Artois date back to the twelfth century. In Italy and Germany, ancient and successful wells of this kind exist, but it is only since the commencement of the present century that they have become general in Europe. In and around Paris there were already, in 1845, not less than eighty deep Artesian wells through the tertiary strata into the chalk. The supply varies very much, but is tolerably constant in the same well. A supply of from 80,000 to 150,000 gallons per day is the common yield, and the expense of sinking is extremely moderate. The sinkings for the supply of Paris commenced at Grenelle, in 1833, and continued till 1841, when water-bearing strata were reached at 1,800 feet, at a cost of £15,000. The first rush of water was at the rate of nearly a million of gallons per day, rising 120 feet above the surface. This continued for some time. Artesian wells are common also in England, not only in and around London, where the geological conditions closely resemble those of Paris, but at Cambridge, through the gault, at Liverpool, through the new red sandstone

and elsewhere. The Artesian wells of London are confined to borings through the tertiary into the chalk, and do not include any sinkings to the greensand. The depth of most of the Artesian wells of London is less than 400 feet, and none of them are much above 600 feet. Some enter the chalk to a depth of 200 feet, or more, and therefore obtain their water to some extent from that formation; while others only reach the chalk, and obtain water from the sands. The tertiary strata pierced are rarely more than 250 feet in thickness. The water, when reached, seldom rises higher than from 40 feet to 60 feet below the level of the Thames high-water mark, and thus considerable expenses are incurred in lifting it. The wells at Cambridge penetrate the gault to the lower greensand at a depth of from 100 feet to 150 feet. The cost is small, and the supply at first rose to or above the surface. It is now 10 feet or 12 feet below. The supply is large and steady, and the number of wells within a few square miles amounts to several hundred. The wells in the new red sandstone at Liverpool and elsewhere are also very numerous, but nowhere very deep. The quality of the water obtained from Artesian wells is a matter of importance. Water passing through a course of strata absorbs mineral matter; but clay is capable either of removing mineral salts from water when they are already present, or yielding various salts if the water be pure;—and thus waters passing through a great thickness of clay may be either remarkably pure or very hard. Of the different minerals found in water there are some that produce hardness, and interfere with the use of the water for detergent purposes, though not otherwise injurious. The alkaline salts render water soft, and thus the large quantity of salts of soda and potash in some of the waters from deep wells does not interfere with their value for household purposes. Carbonate of lime and magnesia, on the other hand, and the salts of iron, though they render water hard, leave it well fitted for drinking purposes. A fifth class of springs is somewhat exceptional, occurring in connection with disturbances of strata, or the presence of metamorphic rock. Such springs are charged with mineral matter and gases, including free carbonic acid gas, nitrogen, hydrogen, oxygen, and sulphuretted hydrogen gas, with a long series of salts of most of the metals. A large quantity of matter is brought by these springs to the earth's surface from the interior, upwards of 16,000 tons weight per annum of various salts being estimated as brought up to the surface from the mineral springs of the central plateau of France. These springs are thermal, or possess a temperature higher than the mean annual temperature of the place at which they emerge. This temperature varies, and sometimes reaches the boiling point. The water rises from great depths, and often in large quantities. These springs are found in all parts of the world, and at all levels above the sea, but they are usually most abundant in mountainous regions, or near volcanoes. The flow of springs is not always uniform, but deep springs are more uniform than those which come from near the surface. For the cause of small and irregular variations we must probably look to the effect of the seasons, but there are marked periodical variations of supply in particular cases that require a more definite explanation. They are known as intermittent springs, and are almost confined to limestone districts. The river Mole, in Surrey, issuing from the chalk, is an example of this kind of spring. It appears abruptly at intervals, which are nearly regular; then runs strongly for a certain period, and as suddenly stops. There probably exists in the chalk hills adjacent, a reservoir filled from the rock above, but with only one outlet, which by some accident of the stratification, curves upwards a few yards before turning down again. So long as the water in the reservoir is not higher than the top of the curved part of the water-way no water can run out, but as soon as this happens, the bent tube acts as a siphon, and when it once begins, continues to carry out the water till it has emptied the reservoir. Such are the phenomena

of springs, natural and artificial, and such the methods adopted by nature and imitated by man to bring the water from the interior of the earth once more to the surface. Let me now point out the application of this great subject to the supply of towns. Some arrangement that shall secure a permanent supply of water for cities is essential. For this purpose most large towns are situated on, or near, running streams. But as the town increases, the waters of the stream become reduced in quantity by the large use made of them, and deteriorated in quality. Wherever there is a large population the sewage is in excess of the demand of the agriculturist, and is conducted into the nearest running water. Thus the waters of the river as it passes each town become smaller and more impure as the need of water becomes greater. Springs are resorted to for potable water, and the river water is only used for washing. Rain-water is collected and stored, but rain-water in a town is rendered foul by the admixture of smoke and vapours, and the supply is of little value. Means have been resorted to from time immemorial to obtain and conduct water from natural sources of supply to large cities. The Romans obtained water in this way from distant places, and conveyed it by aqueducts to the spot where it was needed. Long before the Romans, the Greeks had conveyed water over the surface in closed pipes, taking advantage of the fact that water stands at the same level if there is free communication, no matter how irregular the form and dimensions of the channel. These methods are resorted to at the present day, and with similar success. But a supply of water is not a thing that can be secured easily and without cost. It is an engineering operation for which the aid of the practical geologist must be sought. To obtain pure water for a town, resort must be had to contrivances suggested by, or adapted to, the physical condition of the country surrounding the town, and thus, while in some cases springs may be resorted to, in others rivers or canals may be used; in others, streams may be intercepted at or near their source; in others, mountain-lakes or tarns may be rendered available; and occasionally the rain-fall of a limited district may be collected and stored in reservoirs, whence the water is carried underground or on the surface to a reservoir near the place where the supply is needed. Examples of all these methods may be found in the various towns of England. There are certain limits to the supply of water from springs even the most favourably circumstanced, which now require consideration. Chalk, or loose sand and some sandstones, yield a large quantity of water, replaced from time to time by rain, and the quantity contained in a given area of rock may exceed the quantity required for the town on the surface. But it by no means follows that water is obtainable because it is present in the rock. The loosest varieties of rock are sufficiently close to offer difficulties to the free passage of water; and even from wells of exhaustion the quantity of water removed in a given time is not only incapable of being increased, but the rock is only drained of water within the content of a cone whose base is at the surface and whose apex is at the bottom of the well, and the area of whose base is rarely more than half a mile in radius. The two rocks that yield the largest quantity of water are chalk and soft sandstone; and in neither of these can more than a million gallons per day be expected from a single well. To yield this maximum, such wells must be more than a mile asunder. It could only be from a natural reservoir of large size, existing under pressure in the interior of a rock, that a large permanent supply could be obtained. The expense of Artesian borings, though varying much according to the particular circumstances of each case, is rarely very great. In Europe, the cost of boring has rarely much exceeded 10s. per foot if the depth is under 200 feet, one pound per foot if from 200 to 500 feet, two pounds a foot from 500 to 1,000 feet, and three pounds per foot from 1,000 to 2,000 feet. There are thus powerful inducements at all times to resort to this

expedient. On the other hand, it must not be lost sight of that there have been some very costly instances of failure after boring to a great depth in promising strata. When, owing to increased population, a deterioration of the quality of the water, or a diminution of the regularity of the supply, it is necessary to have recourse to some other contrivance than springs, the old Roman method of constructing an aqueduct has been resorted to. Thus, in the case of London, the "New River" was thought a great success. But opportunities of cutting off water are gradually becoming more and more scarce, while it becomes always more difficult to keep a stream clear. Such contrivances gradually cease to be applicable, and only when connected with reservoirs can this supply be recommended. But the construction of a reservoir is a very serious matter, as is known by fatal experience in some recent instances. It is not twelve months since the bursting of a newly-constructed reservoir in the neighbourhood of Sheffield produced a serious loss of life and property. Thus in this mode of obtaining a supply there are important points to be considered. I may state these as, first, the ultimate source of the water; secondly, the storing it in reservoirs; and, thirdly, the conveying it to its destination. Where there is a natural lake of pure water sufficiently large and well supplied to ensure a permanent supply, no better source can exist. The cost of conveyance is often a barrier against the adoption of such plans; but the possession of a natural reservoir, always full of the purest water, is no slight matter. But if there is no lake, natural springs, if sufficiently large in quantity and good in quality, may be made use of. Thus many of the sources of the Thames are powerful enough to be worth taking for the use of London. But to this there has always been a strong objection. The quantity of water entering the sea at the mouth of the Thames is so little more than sufficient to ensure a permanent stream that it cannot afford to lose any tributary, however small. Even when a single spring can be taken it rarely happens that the flow is so regular as to be sufficient without a reservoir. In hilly districts it is usual to take advantage of natural irregularities of the land, and select the head of a valley, where a convenient space can be enclosed. Such embankments are not always dangerous; but a weak point in the stratification may be the cause of an accident, as well as faults of construction. Reservoirs are necessary where the rainfall of a district is to be collected and transferred to a distant spot. In Lancashire and Yorkshire there are several instances of this arrangement. The rainfall of the district, the form of the collecting ground, the rock of which it is composed, and the dip of the rock, are matters of inquiry, and need the knowledge and experience of a geologist. Manchester is supplied from the drainage of a gathering ground of 18,000 acres, at a distance of sixteen miles from the city; Liverpool, from an area of 10,400 acres, twenty-six miles distant; Newcastle-on-Tyne, from 4,000 acres, twelve miles distant; Bolton, from 400 acres, four miles distant. The lecturer, in conclusion, gave a brief notice of the water contents of the various British rocks. The upper tertiary of England, and the gravel, afford land springs. It is not till we penetrate the lower tertiary, and reach the permeable sands between the London clay and the chalk, that we obtain large supplies from Artesian borings. The supply from the sands below the London clay is extremely large. Chalk contains an enormous quantity of water, distributed through the mass, though chiefly abundant in the lower part. The lines of first favour penetration, and occasional spaces in the rock are generally full. At intervals in the chalk are beds that hold back water better than the rest. Water may almost always be obtained by sinking into chalk to a sufficient depth. Wells sunk through the chalk into the upper greensand are not always more successful than those terminating in the chalk; but the gaug below the upper greensand being impermeable, water may be expected on reaching this bed. The lower greensands are extremely

supplies may be expected from sinking to the quantity obtainable from a single well, is within a given distance of each other, is the water of the lower greensand is irony if got terop, but when filtered through other beds, when passing through clay, it becomes more le water can be got from the Weald clay, nor ugs sand to be depended on. The Kimmeridge Oxford clay are retentive, and have little ter-bearing beds. Water is to be got between must these two bands of clay, but it depends additions, and its presence cannot be assumed of. The Portland rock includes overlying an underlying sand, the former of which r in crevices, the latter in its mass. The r contain water, the alternation of clays limestones being very frequent. The wells have into the rock to its plane of saturation, or even to the clay, as the limestone does not otherwise gly. Lias holds back water, so that at its con- lower coverts there is almost always a line of d the supply is large and constant. Wells lupper beds of the lias rarely fail in obtaining the quality is not good. Wells sunk through the water from the new red sandstone. Wells new red sandstone are almost certain of suc- wing to the number of close faults, the quantity depended on, and the water is apt to be salt. d sandstone is eminently a water-bearing bed, merous alternations of marl and sand render it obtain water from almost all depths. The limestone is full of cavities filled with water to vel. In the coal measures, and in the moun- zme, wherever there is an impermeable band nta, or at faults, water is found. The faulted f the carboniferous and older rocks in England out the water capacity of the rock. The old one is a variable rock, sometimes containing r in sandy beds, sometimes in cavities, and, at between the strata. There is generally a good ter wherever this rock prevails. In Silurian r is got from faults and fissures, which are very

The limestones of this period are, for the argillaceous, and hold back water. Slates, d all varieties of granite, hold water only in Where there is a considerable rainfall these times afford large supplies. Little dependence ed on them, for the fissures do not communi- y from one to another. A remarkable instance d sinking in granite exists in the island of ere a sinking was commenced in the solid d was continued to a depth of 234 feet, all com-

THE CLAIMS OF AUTHORS AND INVENTORS TO PROTECTION FOR AND PROPERTY IN DESIGNS AND INVENTIONS FIRST PUBLISHED AT INDUSTRIAL EXHIBITIONS.

By THOMAS WEBSTER, Esq., Q.C., M.A., F.R.S.

Exhibitions of products of industry, or industrial exhibitions, owe their origin to this ancient Society, the first and, until very recently, the only representative in this country of practical science. The Great Exhibition of 1851, the parent exhibition of the industry of all nations, drew its first breath within these walls; and most here present know that the International Exhibition of 1863 was entirely originated by this Society; and it is not too much to affirm that the seed so sown has borne fruit in exhibitions in the Rietser lake and in other countries, as well as in industrial exhibitions in the metropolis and in the provinces. Whatever may tend to foster and give permanency to such exhibitions is, it is conceived, well deserving the most careful consideration. The reward of the exhibitors by prize, honorary and pecuniary, is a stimulus not to be disregarded and of a permanent character; but the experience of these exhibitions has produced a strong conviction in the minds of many that, unless something more can be done, unless a more lasting reward and benefit can be ensured to the successful exhibitor, unless he can have property in and protection for the product of his brain as embodied in a particular object, the stimulus will not be sufficient to make such exhibitions permanent and self-supporting. Such exhibitions may, it is conceived, be regarded as *maris*—as places in which products that have received the approbation of competent judges and the public, may redound to the substantial and permanent benefit of the exhibitor. That this operates most powerfully with the established trader, with the capitalist whose products have acquired or may acquire, through the exhibition, a notoriety, and is productive of substantial benefit, will not be disputed; but the exhibitor who has made his first successful attempt in a design or invention may see others reap all the pecuniary benefit, if not the honour, of that upon which they have bestowed neither time nor money. The real question involved in the preceding considerations, is how can such reward be best secured to each exhibitor, and what should be the nature of the reward? This may be looked upon as pre-eminently a "working man's question;" I cannot but regard it as one of the great social questions of the day, in what manner the artisan, the skilled mechanic, the youth just emerging from our educational establishments, can utilise the talents which he may be endowed, so as thereby to advance and rise to that social position which it should be the ambition of all to attain. The exhibition of a successful product of industry may be the first step on the ladder, but may afford no assistance to its retention, or to the attainment of the second or subsequent step. The question of property in such a product, and protection for that property, without which the name of property is an empty sound, whether as a matter of right or of policy, cannot be evaded; is it just that the author should not have property in and protection for the product of the brain embodied in some practical and useful shape, and given to the world for the benefit of his fellow-creatures?

LEVENTH ORDINARY MEETING.

Today, February 15th, 1865; PETER, Esq., Member of Council, in the chair. Following candidates were proposed for members of the Society:—

Mr Sarah, Rectory Grove, Clapham, S.
Mr Andrew G., 17, Sunderland terrace, West-ark, W.

Mr V. N. J., Hollington-house, Newbury.
Mr Archibald, 16, Argyll-road, Kensington, W.
Mr John, Budge-row-chambers, E.C.
Mr Ingh, Chemical Works, New-road, Battersea-

Following candidates were balloted for elected members of the Society:—

Mr Wm, 77, Onslow-square, S.W.
Mr J. Frost, 8, Bloomsbury-square, W.C.

That the author of such useful product so exhibited has no claim for remuneration has not yet been asserted within these walls, but although a proposition so repugnant to our innate sense of justice may not meet with any avowed advocate, there are not wanting persons who, from the views expressed on the subject, can hardly stop short of such a conclusion. They concede that the author is entitled to such product so long as he keeps it to himself; he may hum the tune, sketch the design, or use the apparatus in private, or in his own closet; but if he chooses to publish it, he has, they contend, by such publication, given it to the world; he has thereby dedicated it to the public, and what the public have once acquired they cannot be deprived of, but may utilise to their own purposes without regard to any claim by or on behalf of any other person.

This is the condition under which, at present, the author of any design, or the inventor of any useful product, publishes that design or product at an industrial exhibition. Is it politic or just that such a state of things should continue? Have not such exhibitors a claim to property in, and protection for, the products of their industry? That many persons may be willing to forego any more substantial reward than the glory of the exhibition is no answer to the just claim to substantial remuneration for the time, labour, and skill, which may be their only capital, expended on the product or design, and then first published. The labourer is worthy of and deserves his remuneration, without which it can hardly be supposed that the stimulus will be sufficient year by year to reproduce a succession of novelties by working men; that is, by the individual members of that large portion of the community who must earn their daily bread by daily labour, whether mental or manual, whose only capital in fact is such labour.

Circumstances wholly beyond control may exclude the mass of the people from acquiring property in land or houses, but their attainments and pecuniary means may be adequate for the acquisition of property in the embodiment of the labour of their brains; beyond this they may be unable to advance without the aid of those who are in possession of the capital of accumulated wealth. It has been often remarked that there would have been no Watt without a Boulton, or, in other words, that the most successful labours of intellect would fall still born without the aid of the possessor of accumulated wealth and commercial influence. How these two talents, the capitals of intellect and of money, can be brought together is a great social question, to my mind the greatest social problem for the elevation of the individual from the ranks of the people. The Industrial Exhibition affords one means of facilitating this union; it is, or may become an "Inventor's Mart," as suggested by that eminent philanthropist Mathew Davenport Hill, in his letter to the Mayor of Birmingham (4th Nov. 1850), "as the best or only practicable means of affording the inventor opportunity of negotiating with the capitalist, and to the capitalist the means of forming a just estimate of the value of any invention."*

It is said by those who object to, or view with little favour, the protection to and property in designs and inventions the subjects of registration or of patents, that each author or inventor should trust to the position which his skill will confer upon him with the public, or with his employer; that, in the majority of cases, he will gain as much, or more, by trusting to that than to the rights or property with which the law may invest him. This may be true; but however true, is it any reason for compelling or constraining him to continue in this state of dependence? Does the remuneration or reward so attained, in the few cases in which it is attained, bear in the majority of cases any adequate relation to the acquisition of the capitalist? Can any reason be assigned why the law should not recognise property in those creations which had no anterior existence,

to which as the offspring of the individual brain the right and claim, until published or disclosed, is the strongest possible, namely, the absolute control and possession of its author? This control and possession being parted with, the power of copying and reproducing each object of industry, in spite of and without the consent of the author, is conferred on each visitor to the exhibition without restriction or restraint. Is it for the interest of industrial exhibitions that such a state of things should continue? It can hardly be supposed that the opportunity of exhibiting new designs and products would not be a strong incentive and inducement to the production and exhibition of objects of interest to be so submitted to the judgment of competent persons, if some portion of the benefit to result from a favourable judgment were reserved to the exhibitor. As the law now stands such future benefit cannot be received without the preliminary steps for registration under the Designs Act, or for provisional protection under the Patent Law Amendment Act, 1852, having been taken. The cost of such steps would, in the majority of cases, be absolutely prohibitory; it is one of the prominent defects of our present laws for acquiring property in design and invention, that a substantial expenditure, and one which in many cases is prohibitory, must be incurred before any adequate trial or judgment can be had. The remedy is very simple. Let an Act be passed allowing the place of such Industrial Exhibition to be registered at the Board of Trade or other office; let it be enacted that the author or inventor of any design or invention first published at such exhibition shall be entitled to all the privileges of the laws relating to property in designs and inventions, as from the date of the opening of such exhibition, provided advantage be taken thereof within one month after the close of the exhibition. Under this state of the law fair and reasonable opportunity would be given for the fusion or union of the capital of intellect and that of wealth, and one step in advance would be taken for removing the barrier now placed to the progress of intellectual or skilled labour in any new domain of industry.

The course proposed has the authority of precedent. In the Session of 1851 was passed (14 Vict., c. 8). "An Act to extend the Provisions of the 'Designs Act, 1850,' and to give Protection from Piracy to Persons exhibiting new Inventions in the Exhibition of the Works of Industry of all Nations in One thousand eight hundred and fifty-one;" and in the Session of 1861 an Act, with the same object, and recognising the same principles, was also passed for the International Exhibition of 1862. It may be a question whether the details and machinery of those Acts might not be modified with advantage, but their principle is the same as is now suggested and contended for, and appears to me both just and politic. The working of the first of these Acts, called "The Protection of Inventions Act, 1851," afforded strong evidence of how much might be done towards protecting inventors against their own ignorance. Some plan or system for the identification of the design or invention is necessary; The identification of a design presents no difficulty, but the proper identification of an invention is not without difficulty, and according to the plan adopted in that Act a certificate of the sufficiency of the description of the invention to be registered under the provisions of the Designs Act is a condition precedent to obtaining the benefit of protection for and property in the invention. Although there was no power of refusal of such certificate if the description was adequate, upwards of 70 persons out of about 600 applications, or more than one-tenth, declined to proceed further on the suggestion of myself (to whom, in conjunction with your secretary, Mr. Le Neve Foster, the administration of that Act was entrusted), that, looking at the character of what was proposed it could hardly be worth while to proceed any further with the registration. The principle of the provisional registration then first adopted was carried out in the Patent Law Amendment Act, 1852, the Act of the next session,

* See evidence on Patent Law before Select Committee of House of Lords. Session, 1851.

and is now known as the Provisional Specification, the sufficiency of which is certified by the Law Officers of the Crown. The Royal Commissioners, in their report just issued, have recommended that the application for a patent should be subjected to a preliminary examination as to novelty. The protected exhibitions now contended for would at once bring to the test the merits as well as the novelty of designs and inventions, and thus in effect go beyond what is recommended by the Royal Commissioners as one of the improvements of the present patent system, thus tending to diminish those inconveniences which the Royal Commissioners consider as incident to any patent system, and as the price which the public pay for any patent law. The course now suggested assumes the justice and expediency of some patent law, that is, of some mode of rewarding or remunerating those who are the first to publish new designs and inventions applicable to the industrial arts. That the present patent law admits of, nay requires great improvement cannot be denied; the evils of the indiscriminate issue of patents are seen in the litigation which is the subject of such just complaint. This very litigation is one of the indications of the overwhelming power of capital. Hitherto the patent system of this country has been an unequal struggle between the inventor and the capitalist, in which the latter has had the advantage. In what position would inventors be placed if left absolutely at the mercy of the capitalist, as would be the case if they could acquire no right in their invention to be protected by the strong arm of the law? The real difficulty lies in the mode of protecting the property which the law recognises. Is it a proper course to refuse a recognition of property because of the difficulty of protecting it? Why should not the attempt be made in the direction and manner indicated by the authors of the Patent Law Amendment Act 1852, which, as regards all remedial measures, has hitherto been a dead measure? To pursue this question further would be to travel rather out of the present subject, but these considerations will naturally arise when the claims of the working classes to property in the products of their industry are insisted on. If such property cannot be secured and protected better than hitherto, there will practically be one law for the rich and another for the poor. The Royal Commissioners have recommended that the adjudication of these rights should be left to a judge, aided by skilled assessors; a suggestion which has been repeatedly made and supported by the authority of those most conversant with the working of the patent system.

The promoters of industrial exhibitions will add greatly to the claims which they have on public gratitude, by directing and concentrating attention on the means by which practical and available protection can be secured for the creations which these exhibitions call forth for the first time. The exponent of an existing trade may find his reward and remuneration in the publicity given to the labour and capital under his direction and control, but the ingenious artist or artisan is in a very different position, and must rely on the protection of the law for that independence to which he is entitled.

It lies on the opponents of the views now contended for to show why there is to be property in and protection for a design and not for an invention. The inherent difficulty of the two subjects is matter of degree and administration. It is hardly creditable to our national character that the admitted abuses should be permitted to continue, without even the attempt to apply some of the obvious remedies which have been not only suggested and recommended, but actually provided for by the legislature.

It also lies on the objectors to the existing system, as those who contend that an exclusive privilege is an inconvenient mode of reward, to point out a better. Such a privilege as I endeavoured to show in my last communication to the Society,* was no violation of the principles of free

trade, inasmuch as it was only the means, the best hitherto devised, of creating and calling into existence the trade which when so created would be free after the limited terms thought necessary for such creation. If the term is longer than necessary, shorten it. This the system of periodical payments practically does. If the exclusiveness creates any practical inconvenience, let the public have that which the Royal Commissioners recommend that the Crown should have, in the right of purchasing a license for a sum to be settled, in case of difference, by arbitration.

Upwards of twenty years have elapsed since in this room, and on every convenient occasion, I have dwelt on the evils of the system, and pointed out the remedies now suggested; those evils are mainly defects of administration. To cut the Gordian knot by abolition is a remedy not likely to meet with favour until other remedies have been exhausted.

The claims of the author, in whatever department his intellectual capital may be invested, are, to my mind, stronger than the claims of the possessor of a transmitted inheritance, however considerations of public policy or expediency may allocate the relative claims of its possessors; and if circumstances exclude any considerable portion of the people from one description of property, do not deny to them the enjoyment of that which they have the power to create for themselves.

DISCUSSION.

Mr. CAMPIN was glad to find that Mr. Webster had touched upon the general question of protection to inventions in his paper, because the special subject of protection at Industrial Exhibitions must be treated as part of the larger question of the amendment of the existing patent laws. It appeared to him that if they gave protection to exhibitors, and then left them to the tender mercies of the Patent Office in the state it was now, they did but little for their benefit, because it was next to impossible for the great majority of exhibitors at Industrial Exhibitions to pay the successive £5, £50, and £100 fees necessary to secure patents under the present system. Moreover, he was disposed to think that the period of one month suggested by Mr. Webster as that within which application for a patent must be made, was wholly inadequate for the purpose, but this was a mere matter of detail. There were some other points not taken up in the paper which he thought would add to the strength of the case. These exhibitions contained not only designs for articles of utility, but also artistic designs. It so happened that, under the Copyright Act, in the procuring of which this Society was mainly instrumental, a man, at the cost of one shilling, could obtain a copyright for his life and seven years after his death, for an original drawing, painting, or photograph—the latter frequently not being the result of any original conception at all. It seemed strange that a man should be able to acquire a property in a production of that class on such easy terms, whilst if he turned his attention to a mechanical improvement or a chemical discovery, he could not obtain protection without incurring the heavy expenses of a patent. All who knew anything of the subject must agree that it was of vital importance to these industrial exhibitions, which were so widely extended throughout the country, that there should be some kind of protection for the original efforts of ingenuity which were there displayed, because he did not think mere honorary distinction would be a sufficient stimulus to promote the permanent success of those exhibitions.

Dr. PANKHURST had listened to Mr. Webster's paper with great interest, and he merely rose to suggest that they ought to distinguish between the general question as to the policy of a patent law and the particular question more especially treated in Mr. Webster's paper. If he understood him aright, Mr. Webster simply submitted the following question—that, assuming there ought to

* See *Journal*, April 22, 1864.

be property in and protection for designs and inventions, and assuming the policy of the two special acts which were passed to protect such inventions and designs in the case of the two International Exhibitions, on what ground could they withhold such protection in the case of the numerous industrial exhibitions now being held in various parts of the country, the importance and value of which were becoming more and more appreciated? He could not resist the force of the position which Mr. Webster sought to establish. As a matter of justice and right it was quite clear that a man who exhibited an invention under those circumstances ought to be protected by some such plan as that now suggested. That, however, would not relieve him from the difficulties in which he would be placed when the invention, if it were a valuable one, became the subject of contest between himself and the capitalist, a difficulty which he was afraid they could not entirely get over. Whether the plan suggested by the Patent Commissioners might relieve the poor man from the unequal burden of this contest he was not prepared to say. The purpose for which he rose was to express his approval of the simple proposition contained in the paper, and on the grounds of analogy and consistency, as well as plain justice, he conceived some such plan as that suggested ought to be adopted.

Mr. F. J. BRAMWELL would have been glad, before addressing the meeting, to have heard some of the views advocated on the other side of the question. He would say, at the outset, he was in favour of protection to inventors. Mr. Webster had proposed, and the two previous speakers had supported the proposition, that if the protection afforded to inventions at the two Great Exhibitions in this country was right in principle, the same should be afforded in other exhibitions of a cognate character. The proposition extended to inventions only, inasmuch as designs were already protected by legislative enactment. When they came to inventions it was a matter of greater difficulty. Mr. Webster proposed that the protection should be extended to one month after the closing of the exhibition; but he (Mr. Bramwell) thought the inventor should be required to deposit what might be called a provisional specification with his invention; and unless that document was very carefully drawn there would be considerable difficulty. It might be the case that an invention contained some things which were old and some which were quite new; and if a man said the model he exhibited was the thing for which he claimed protection, and did not at the same time furnish proper particulars, there would be great difficulty in giving him a patent, even if he could afford to pay for one at the present high rate, which, in his (Mr. Bramwell's) opinion, might with advantage be lowered. Allusion had been made to the letter of Mr. M. D. Hill, suggesting that these exhibitions should be regarded as "inventors' marts;" and no doubt that was the very thing required. A man might produce an excellent invention, but at the same time be without the means of introducing it to the world; and even if he had connections which would serve that purpose, he might hesitate to bring his invention before them without protection. The great difficulty a working man experienced was to get his invention considered and appreciated by capitalists. With regard to the general question as to the policy of a patent law, it might be said that those who were opposed to protection consisted of two classes—those who admitted the necessity for a law of copyright, and those (a small class) who went to the extent of advocating the abolition even of the copyright in books, as well as of the patent law. He had formerly heard a well-known Professor of Political Economy advocate the abolition of protection for manufactures, and the retention of it for designs and books; but he had since heard the same gentleman declare the advance which had taken place in his opinions, which now went to the extent of abolishing copyright altogether. There was at least a

consistency in this, though how anyone could maintain such a doctrine he (Mr. Bramwell) was unable to understand. There was, however, great inconsistency in those who would give protection to a man who designed a pattern for a carpet, but would give no protection to the man who invented the loom in which the design was woven. These were the two classes who opposed the protection to inventions. What were the grounds on which this opposition was supported? People did not, as a rule, consider the actual manner in which an invention was born and brought to light. They started with the assumption that if anything good was invented everybody would use it if it were not hampered by a royalty. If, however, they looked through the most meritorious inventions, what did they find to be the fact? A specification of the invention was deposited; but there was utter apathy on the part of those to whom the invention would be most valuable, and the patentee was obliged to spend years of time and a great deal of money in order to induce people to take up a thing which was for their benefit. He ventured to say that ninety-nine out of a hundred useful and good inventions had lain dormant for years before any person would take them up. In illustration of this assertion Mr. Bramwell mentioned the case of the fish-joint for rails, which, he said, was now acknowledged to be worth £150,000 a-year to the railways of this country, but it required six years' unremitting exertion on the part of the inventor before he could get the railway companies to use it at all, although the royalty demanded was not large. That was sufficient proof of the lack of eagerness on the part of the public to take up really good and valuable inventions. He firmly believed that patents, so far from being an obstruction to invention, stimulated it. He would not stay to go into the subject of the justice of protection, or of the right of the inventor to it, for political economy did not recognise such things as justice and right, but only acknowledged the force of expediency. He would, however, say that it was expedient for the community that protection should be afforded to inventors. On the other side of the question it was argued—"Do not protect inventors by patents, but let the inventor obtain his reward by the fame he achieves for himself." Others asserted that his reward would come in the ordinary course of trade, through the development of the invention itself, and from the inventor becoming the manufacturer of the article. Dismissing at once the idea that the "glory" of an invention would act as a stimulus to inventors in the present strictly practical age, he would dwell for a moment on the next argument, that inventors should become manufacturers. In answer to this they had the fact before them that the great substantive inventions of this country were made not by persons in that particular class of manufacture, but by outsiders. A man who had practised a considerable business for a number of years had got his mind in a particular groove, and he preferred to go on in the way he had been long accustomed to. He might make some little difference in detail, but he was not the person to look to for great substantive improvements. Taking the great instances of inventions of later ages, they found that Watt, the inventor of the then called fire-engine, was by trade a watchmaker; that Arkwright, the inventor of the spinning mule, was a barber; that the inventor of the power-loom was a clergyman; that the inventor of the screw-propeller (or at least the man who brought it into practical use) was a farmer; and the inventor of the electric telegraph, a musical instrument maker. This was sufficient to show that the great and sterling inventions did not emanate from those who were engaged in the particular trade to which those inventions were applicable, and under such circumstances he asked, what would be the condition of the inventor without protection? A further objection to the absence of protection to inventors was, that it would lead us back again to the old secret systems in the workshops, as

that would then be the only protection an inventor could avail himself of. Crompton, the inventor of the mule, found a ready market for all the yarn he could make, and the question arose how did he make it of that quality? To preserve his secret he barred up his windows and barricaded himself in his factory. Then people climbed into trees to overlook him; others tried to tamper with his workmen, till at last he agreed to dispose of his secret to twelve persons, but only one out of the twelve paid him the price agreed upon. That was a fair example of the evils that would arise if protection were abolished. A favourite argument against the patent law, as it now existed, was, that out of the 3,000 and odd patents applied for every year, more than 1,000 were allowed to expire at the end of six months, and thus became the property of the public; that at the end of two years and a half more another 1,000 dropped off; and that, comparatively, few out of the 3,000 paid the final fee of £100 for the full period of fourteen years. He believed it to be the fact that only about 6 per cent of all the patents taken out were carried to the point of paying the £100, and he was aware that was a strong objection against protection. But in his opinion the public were greatly benefited by such a state of things, as they had the advantage of the publication of this large number of inventions; and as the patents lapsed it could not be alleged that they were any obstruction to progress. He thought, however, the existing patent law was capable of great amendment and improvement. The great point to be enforced was, that every inventor should honestly and truly specify what his invention really was. He assumed the law never meant that it should be otherwise; but it might truly be said "the law was made of none effect;" inventors sheltered themselves under the elastic term "combination," which was in some cases carried to such an extent as to shut out many really useful and good inventions, inasmuch as there was a fear of infringing that which had already been specified under the convenient term "combination." He, considered unless a man specified what he wished to be protected in such definite terms as could be understood by persons of ordinary intelligence reading the specification, he ought not to receive protection, and if this were done a vast amount of the objections they had heard against the patent laws would be done away with.

Mr. W. HAWES said it was very difficult to treat a subject on broad and general principles, after it had been reduced by each successive speaker into a criticism of details. Those who objected to the patent laws justified their objections on the principle that the operation of these laws was unjust to the community, that they were calculated to deter and not to stimulate invention, and were in every respect injurious to the interests of the public. He took up the question on the broad principle whether the public really gained or lost by the operation of the patent laws. It was matter of history that the great majority of inventors were amongst the most unsuccessful men in the world, and that the parties who really benefited by the patent laws were those who speculated and traded in other people's inventions. The patent laws were evaded in every step of their progress; moreover, they could not be supported on the principles of political economy. He had been surprised at the remark of the last speaker, that political economy was based neither on right nor justice. Political economy, however, was a science of modern days, which had risen with civilization and with the progress of knowledge, and to say that that science was based neither on right nor justice, was an expression of opinion which he hoped would not be supported by the enlightened and educated classes of the kingdom. The whole liberties of the country were based upon the truth of political economy, and if those principles were not those of truth and justice, he would ask what principles they had to guide them in the administration of law and equity throughout this realm? They had had paraded before them a great many objections to the patent laws, but those objections had

not been urged upon sound principles. They had been told that there was protection by law for a design, while the machine by which the design was produced was unprotected. He thought such a statement was made in ignorance of the real state of the case. The law of copyright in books had been compared with the patent law. Now what was the operation of the law of copyright? The law of copyright in books prevented any one reprinting a book word for word as it was issued from the press by the author, but it did not prevent a man getting all the information he could out of the book and reproducing it in another form. He might use this information in every possible way, so that he did not absolutely reprint that identical book, or such a colourable imitation of it as would mislead the public. There was no similarity whatever between that and a law which said a man might take out a patent, dividing his claim, as had been explained by the last speaker, into five or six parts, and then if one of those parts were applied to a purpose quite dissimilar to the original intention of the patentee, it could be made the subject of legal proceedings. The two things, copyright in books and the patent law, were very dissimilar; and they had the authority of the first engineers, and of men most distinguished for discoveries in modern times, that improvements were impeded and checked by claims being made upon them for royalties for the use of certain parts of inventions, which it was said belonged to patents taken out for entirely distinct purposes. The designer of the *Great Eastern* steam-ship, in the application of modern improvements to uses to which they were never applied before, was perpetually fettered by claims for the alleged infringement of patents. He therefore said the patent laws checked invention, and did not benefit the real inventor. The case of Watt had been referred to, but it was notorious that he was nearly ruined by constant litigation in defending his patents, and it was only by the pecuniary assistance he received from Boulton that he was kept from sinking under the difficulties to which in this way he was exposed, by the operation of a law now supported in the interest of inventors. Many of the most important discoveries had never been patented. Gunpowder, paper, and glass, among many others, were discoveries which were never patented. These discoveries were made without a patent law, and the best practical inventions in all ages were those which had never been made the subjects of patents. Now what was the origin of the first patent law in this country? It was nothing more than an agreement between the throne and the subject to perpetuate monopolies. Previous to the time of James I. patents were granted by the Crown on certain pecuniary conditions, which led to enormous abuses. The people resented that state of things, and the result was the limited monopoly afforded by the patent laws. Patents were, however, admitted to be a monopoly, and he believed that no kind of monopoly whatever was useful or beneficial. The argument now used in support of the patent laws was the same as that urged in favour of the exclusion of foreign corn from this country. Nevertheless, the result had shown that unrestricted competition was a good thing for the community at large. Would they wish to go back again to the monopoly in corn by the farmers of England? He might illustrate his views at any length in this way. They must look at it, however, as a great national question, as a people's question, and not only as an inventor's question. Let them look at the statistics relating to patents. The 3,200 patents applied for in the year were reduced to 1,900 at the end of the first period; at the end of the second, or 550 period, they were reduced by 539; and proceeding further, they found that out of the whole number of patents taken out, but 140 were considered worth the payment of the £100 for the continuation of protection through the whole term of 14 years. They might look at the question in another point of view. Patents were frequently taken out for the purpose of advertising articles as being produced under letters patent. People

were apt to think a patented article must of necessity be superior to others, and he believed this was a means often resorted to to puff an inferior thing; but this would, of course, last only a limited time, when the patent was allowed to drop. This was the history of all but a small fraction of the patents taken out. To revert for a moment to the paper now before them, it was proposed by Mr. Webster to give some kind of protection to inventions brought before the public in the industrial exhibitions which were now taking place all over the country. If there was any good at all in the patent laws they would not stop where they were. If they encouraged the working classes of the country to expose their productions to the public eye in those exhibitions, he did not see how they could stop short of giving them an adequate amount of protection for those productions. Having passed Acts for the wealthy exhibitors in 1851 and 1862, they could not refuse the same protection to the exhibitors at these industrial exhibitions. The views of the late Mr. Brunel and also of Sir William Armstrong on the subject of the patent laws were well known; and although he (Mr. Hawes) had not always advocated the principles he now supported to the full extent he now did, yet he had done so in this room for the last fifteen years. But the supporters of the patent laws, feeling the difficulty of maintaining the existing laws, suggested, as a means of meeting the evils daily arising from the flood of sham and useless patents, that there should be such an examination of inventions as to ensure that no patent should be granted except for that which was absolutely new; but who was to be the judge to say whether a given mechanical, chemical, or scientific process was new? If such a tribunal as that were established, it was probable that many important discoveries would be nipped in the bud, and would be condemned as worthless. Where then were the persons to be found to say whether an invention was useful and also new? The only alternative left was to make the cost of patents so small that every one could obtain them. Looking, then, at all the difficulties of this important question, considering it from a national and not solely an inventor's point of view, he believed the time would arrive when all would admit that the patent law was an injury both to the public and to the inventor.

Mr. BRAMWELL explained, that what he intended to say was not that political economy was not based on truth and justice, but that it was not its province to deal with abstract justice or abstract right, but only with the question of public expediency.

Mr. LEVERSON was glad that the question had at length been referred to general principles by Mr. Hawes, for, the principle of giving property in inventions once conceded, all must concur in the admirable suggestions put forward by Mr. Webster in his able paper, but there was no use shutting our eyes to the fact that the real question to be determined was should any patent laws exist at all. And here he begged to state that, although ten years ago he had written upon this subject without hesitation, and with all the positiveness and dogmatism of a young man, he now, while entertaining precisely the same views, expressed them with greater diffidence, and entertained far more respect for what had to be said on the other side.* He begged at the outset, though agreeing with Mr. Bramwell in the main, to express his entire dissent from what he said on the subject of political economy. It was to political economy we owe our knowledge of the reasons for permitting any right of property at all, and it was to the principles and teachings of economic science to which recourse must be had, not only to support a property in thought, but all kinds of property. In answer to Mr. Hawes and his appeal to general principles, he would urge that all rights were the creatures of the law, and that the object in giving a right of property in the pro-

duce of labour was to give an inducement to labour, and that but for this we never could have emerged from the rude state of barbarism; moreover, the greatest inducement to labour, and at the same time the least, i.e., the cheapest, was to give to the producer the right to possess and to dispose of the produce of his labour. The law said if any one actually manufactured an article it became his property to keep or to dispose of—if he sold his labour that he should be entitled to his wages; the principle then of the right of property in the produce of labour once established, it lay upon those who desired to withdraw any particular produce of labour from the operation of that principle to establish a case for doing so. Did they propose any mode of remunerating the inventor for his invention, cheaper to the community, or affording a larger inducement to labour? No, they proposed, instead, to abolish the patent laws; that is to say, to destroy the property altogether, and this on the plea that the present laws were detrimental to inventors themselves. Of that the inventors were the best judges, and the answer to it was the immense number of patents of which we had heard. But we were told that it was not the inventor who was benefited by the present laws, but persons who had never invented at all. He admitted there was a great amount of truth in this, but the meaning of it was that the inventor, having had conferred on him a property (of which the abolition of the patent laws would deprive him), owing to causes presently to be mentioned, chose to exercise his right of property by parting with it; the right to dispose of his property being, he (Mr. Leverson) submitted, an element in its enjoyment. But what was the real cause of his having to dispose of his property for, often, so inadequate a consideration? Not the law, which gave him the property, but the defects in that law which only gave it on costly terms, and the still greater defects of that law—its expense, vexation, and delay in preserving to him his enjoyment of that property. Reference was made to certain grand inventions which had never been patented, but this certainly was not an argument upon general principles, and was best met by that great mass of inventions which were patented. As to the costly machinery of the patent office, this was paid for by the patentees, and not only so, but there was a large overplus; he claimed that the fees taken from inventors should be only sufficient to cover the expense of registration, and of affording that special kind of protection which the nature of the case demanded, and the necessity for which was one of the natural difficulties of the case. And here he begged to deprecate an appeal to the history of the patent laws, or to the history of any other law as being supposed to afford an argument either for or against it. This was not a question of an agreement between the crown and people; the question was not one of history, but of social science and of jurisprudence. Was it or was it not desirable in the interests of society that this or that right should be granted by the law? This appeal to antiquity was the more to be deprecated from the peculiar mode in which our laws and civilisation had grown up. Our neighbours (the French), having an accumulated mass of evils, got rid of them by overturning the social fabric and commenced building up a new one; we, on the contrary, as we progressed from barbarism, amended here and amended there, leaving or retaining such bits of good (and often a great deal of bad) as had been introduced into the mass, and in this way the patents granted by the Crown having supplied a want felt by society, viz., the right of property in inventions, were retained. That this peculiar species of property, viz., property in thought, was more difficult to protect than any other was true, but the way to remedy this was not to say, "We won't give any property or protection at all," but to devise proper means to give the most effectual security possible. The real difficulty—the real defect—lay in the law, and to remedy this, reliance must not be placed on the lawyers—they would afford no help; but here the public

* "Copyright and Patents, or Property in Thought." By Montague R. Leverson.

must help themselves, and in this the Society of Arts could do great service. By the present vexatious, dilatory, and expensive system of procedure justice was not done, the expense, vexation, and delay being often a greater injustice than the original wrong. If a rational system of litigation were to be established, it would be found that the greater part of the evils complained of in this, as in every other department of law, would disappear, and all or nearly all Mr. Hawes's objections to the patent laws would vanish, they being, in fact, the results of the defects of legal procedure rather than of any real difficulty in the nature of the subject. If, instead of the present system of barbarous jargon, absurdities and fictions, when A complained of B, he were to complain in person to the judge, and the judge were to summon B before him, once the parties brought face to face before the judge, nine out of every ten disputes would be immediately determined. With regard to patents, the cry of monopoly was raised. Of course, all property was a monopoly. If this coat was his, and he was to have a monopoly of wearing it, so did an invention belong to the inventor, and he ought to have a monopoly in it. The owner of the coat had a right to the monopoly—the owner of the invention had a right to the monopoly also. The law, and the law alone, gave the one, and he hoped the law would never cease to give the other.

Mr. MUNRAR, as one who had been largely engaged in the organization of Industrial Exhibitions in the metropolis, desired to express his deep obligations to the Society for affording this opportunity of ventilating a question of so much interest and importance at the present moment. He considered that the principle which was applied in the case of the two Great Exhibitions, and which was about to be extended to the Dublin Exhibition, ought fairly to be applied to Working Men's Exhibitions. At the present time inventions shown at these Industrial Exhibitions were so entirely without protection that any person was at liberty to take a sketch and make the best use he could of any article there exhibited, from which, however, the articles in the Great Exhibition were protected by a special enactment of the legislature. He wished to state that a deputation on this subject to Mr. Milner Gibson had been received in a manner which led to the belief that the measure of protection sought for in these cases would be afforded.

Mr. G. F. WINNER, F.R.S., said the arguments on both sides of the question had been so fully entered into by Mr. Bramwell and Mr. Hawes, that he would only refer to one point on which he especially disagreed with the latter gentleman. It had been his fate to have been thrown a good deal in the way of patents, both as a patentee himself and as having received a good deal of annoyance from the patents of others; and with a full knowledge of obstructive patents in his mind he would say that a great number of inventions could never have been carried out to anything like perfection without some such protection as was afforded by patents. Therefore, on the broad view of the subject, he considered patents were a benefit to the community. Then there was the matter of the temptation to work in secrecy. In many trades, some years ago, secret working was carried on to a great extent, and the evils of this were well known. If protection were abolished this system would no doubt be returned to, and there were many processes, such, for instance, as the manufacture of magenta dyes, which could have been thus carried on. How much advantage would the public have lost by this in the way of improvement? There would not then have been, as had now been the case, many minds brought to bear upon the subject, and the variety of colour and improved processes now in use would have long remained undiscovered.

After a few words from Mr. MUNROON,

Mr. CLARKE suggested that a useful hint on this subject might be gained from the practice of other countries. In France a patent could be taken out for £4, in Belgium for £10, and the American system had been found to

work well generally. He could confirm the statement of Mr. Bramwell as to the difficulty of getting an invention practically before the public, inasmuch as he had himself been fifteen years trying to introduce an invention, and had been obliged to obtain a prolongation of the protection. In one instance in particular, in which a saving of many thousands a year could be effected in a particular branch of manufacture, the invention was as yet only in the infancy of its practical application. He confessed he had no great faith in "glory" as a stimulus to invention.

The CHAIRMAN, in closing the discussion, said he would trouble the meeting with very few observations. He might say that the paper before them originated in the general desire that was entertained that the working men who exhibited their productions at the different exhibitions in London and in the country should have protection for the novelties they placed before the public. Such a desire was only reasonable, and he thought the legislature was in duty bound to accord that provisional protection at such a cost as would be within the means of the working classes. The discussion had naturally extended to the consideration of the general question of protection by patents. Mr. Bramwell, he thought, had pretty nearly exhausted the arguments in favour of patents, and some of the objections of Mr. Hawes were doubtless worthy of consideration. He would confess that, as far as investors were concerned, he believed few reaped anything like a proper reward for their inventions, and in the generality of cases he thought they did not benefit by the patent law. But if the question were asked, who did get the benefit? his answer was, the public; and if they could not support patents on public grounds, the sooner they were abolished the better. It required more than mere invention to give a thing stability. It required experiments, frequently of an expensive character, and a large outlay of capital before it could be even fairly tested, because tests which succeeded on a small scale often failed when applied commercially on a large scale. The assistance of the capitalist would not be given, if it were not for protection; indeed, the most important inventions this country had witnessed would never have been brought to light but for the patent laws. He believed it was the invention of the country, the capital which developed it, and the protection which the patent laws afforded, which enabled us so greatly to multiply our resources and extend our enterprise. They must not be unkindful of the obstructions which stood in the way of the practical application of many great inventions. For instance, a manufacturer of a certain textile fabric, employing a thousand looms, might be told by an inventor that he could give him machinery that should weave for 2d. a yard what he now paid 10d. a yard for. The reply of the manufacturer would be, "What am I to do with all my old plant, in which a great portion of my capital is invested? Besides, I don't believe it is practicable to do what you say." The inventor would go to another manufacturer and meet with the same reception. Thus the invention might lie dormant for years, until some one, probably unconnected with the trade, found the capital to bring it into operation, and made a large profit out of it. But it was not to be supposed that this would be done without the protection of the patent law. He thought the expense of provisional protection should be 5s. instead of £5, and to a poor man, to whom £1 was of consequence, it might be reduced to 1s., especially when they saw how many patents fell through before six months expired. They had been told of the great expenses in connection with the Patent office, but these were paid by inventors, and not by the public, whilst the public reaped the full advantage of the great number of specifications which came before the world when the patents lapsed. He concluded by moving a vote of thanks to Mr. Webster for his very able paper.

The vote of thanks having been passed,

Mr. WEBSTER expressed his acknowledgments for the way in which his communication had been received. He

must say, as regarded the speech of Mr. Hawes in opposition to patents, which was characterised by that gentleman's usual ability in anything he undertook, he could not but look upon it as a tissue of fallacies throughout. Was there any analogy between the protection of an invention and the maintenance of restrictive duties on the import of a produce like corn? Was it not a delusion to talk of a comparison between that which gave a privilege for creating a thing, and that which caused the exclusion of a commodity already existing such as corn? The so-called monopolies which were abolished by the Act of James I., were monopolies in the sale of certain well-known articles, which were then restricted to certain privileged persons, but there was no analogy between the two cases. One defect in the present law was permitting actions too readily against mere sellers of articles. Neither the seller nor user, except he was in collusion with the manufacturer, ought to be subject to action for infringement, because there were many innocent usings and sellings, and no doubt, in many cases, black mail was levied on such parties rather than stand the fight of a patent cause in the Courts. One of the improvements which he hoped to see in the law was, that there should be no action for infringement, except under the fiat of some competent person that there were reasonable grounds of action. They had been told about the obstructiveness of patents, and that in many cases they were used merely for puffing an article, but they must be considered a rather expensive mode of puffing. In reference to the argument drawn from the fact that so large a proportion of patents were allowed to lapse without running their full term, it must be remembered that persons having patents often did not go on paying because they might have improvements which would render the former patent nugatory; and so it was often no argument against the value of an invention to say that the patent was suffered to lapse. Then again, it was argued that the invention of gunpowder was not patented; but everything must have a beginning, and the fact that gunpowder, glass and paper had not been patented was no answer to the rapid progress that had been made in various manufactures under the protection of the patent law. Nothing could be more true than the statement that most of the great inventions did not emanate from the persons engaged in that particular manufacture. A person who had a large capital in machinery was generally the last to desire improvement; he would be inclined to suppress invention, and that was one form of obstructiveness which inventors had to contend against. He thought what was wanted in the present day was a concise history of the inventions that had grown up under the system of patents, which would form a valuable contribution to the study of the subject. With regard to the preliminary examination of inventions, he thought in many cases it would save imaginary inventors from the consequences of their own ignorance, though the power of rejection should not be absolute. He hoped this subject would be followed up in the interest of the working man, for it was a working man's question. They could not expect a reform in the patent system to come through the lawyers any more than through the capitalists, as both classes were interested in maintaining the existing state of things.

Proceedings of Institutions.

KNUTSFORD SOCIETY, FOR READINGS, MUSIC, AND LECTURES.—The committee having found that the establishment of penny readings in the town has been attended with more success than could reasonably have been expected, have made arrangements for a course of lectures in addition to the readings. Amongst the subjects are—"Freedom's Battle; or, the Struggle of a Thousand Years," by Mr. John Johnson, of Liverpool; "Jerusalem, past, present, and future,"

by the Rev. John Broad, St. George's, Newcastle-under-Lyme; "The Curiosities of Insect Structure," by Mr. John Withrington, Blackburn; and "The Bow of the Past, and the Rifle of the Future," by the Rev. Samuel Doria, of Wigan. The admission is, in all cases, one penny each, but tickets for reserved seats, at sixpence, are also issued. No donations are solicited, because the system of penny payments for admission renders the Society self-supporting, and avoids the objectionable features of free lectures and readings.

MARLBOROUGH READING AND MUTUAL IMPROVEMENT SOCIETY.—Mrs. Ballour recently gave a lecture here on "Illustrious Prisoners, and what prison hours have done for the world." Out of the wide field comprised in the title, Cervantes, Sir Walter Raleigh, John Bunyan, and a pathetic history of the escape of Lord Nithebdale from prison and a scaffold, were the chief subjects chosen. The lecture appeared to be much appreciated by the audience.

METROPOLITAN ASSOCIATION FOR PROMOTING THE EDUCATION OF ADULTS.—The second annual meeting of this association was held on Wednesday, the 8th inst., at the house of the Society of Arts. Earl Granville, K.G., President of the Association, occupied the chair, and was accompanied by Lord Feverham, Sir T. Phillips, Mr. W. Cotton, Archdeacon Utterton, Revs. H. White, Wallis, Mr. F. S. Powell, M.P., Mr. B. Shaw, and others. The report showed that the work of the Association had greatly increased during the past year. The number of candidates in the elementary examinations had been more than doubled, while in the examinations in religious knowledge, held under the direction of the Bishops of London and Winchester, the advance had been still greater. Several clergymen and managers of schools and institutes had borne testimony to the value of the Society's operations. During the year a number of educational classes, on the principle of those of the London Mechanics' Institution and City of London College, had been established in the district. Female education had formed an important part of the work of the Association. Conferences on subjects connected with adult education had been held, which had been well attended. In order to bring the subject of Adult Education under the notice of the public generally, meetings had been held in different parts of the metropolis, at which deputations from the Committee attended to explain the operations of the Association. Physical education had engaged the attention of the Committee, and at a *fitu* held at the Crystal Palace, on the 27th of June, prizes to the amount of twenty guineas were awarded to successful competitors in athletic sports, and delivered to them in the orchestra of the Crystal Palace, by Mr. Harry Chester, the Chairman of the Committee. The receipts of the Association amounted to £184 0s. 6d., and the expenditure to £190 3s. 11d. The report concluded with an earnest appeal for increased support. Earl Granville said that sitting in that room, where he had often had the pleasure of meeting a portion of the company then present, he could not help advertising in few words to the Society of Arts, to which the room belonged. For more than a hundred years it had been at work encouraging education in different forms throughout this country. There was no doubt that its proceedings had been marked to a singular degree by that stubborn energy which was the characteristic of the English nation; and that a great amount of benefit had been conferred on the arts and manufactures of this country by that society. It was soon after the Great Exhibition of 1851, that the step was taken by the Society of Arts of forming a union of institutes throughout the country, and, when thus united, it obtained for them the legislative powers by which their property was protected. It then became desirable to enlarge and liberalise those Institutions, and make them more active, more agreeable, and more instructive to those connected with them. It was found that, in order to give full effect to the educational objects of those Institutions, it was also necessary to establish some system of examinations, and he thought this was a

most wise step on the part of the Society. He believed the Metropolitan Association (which was in Union with the Society) was established because it was found that, thickly populated as this metropolis was, and great as was the amount of activity that prevailed among all classes, yet the attendance at these examinations was much less numerous than in other parts of the kingdom. The objects the Society had in view appeared to be to give an opportunity to those who were chiefly engaged in labour to redeem time mis-spent, or to continue the advantages of education, which they had only been able to receive up to a limited period of their lives. The advantages of education were said to be so obvious that it was unnecessary to urge them; still he would repeat his belief that knowledge was of the greatest advantage to every class of the community. He remembered that the late Prince Consort, when he used the words "knowledge is power," always added, "and enjoyment too." The Prince Consort, coming to this country as a foreigner, was in a difficult position. It was perfectly clear that if he had arrived here a perfectly idle and uninformed man, he might perhaps have been powerful for harm, but he would have been powerless for good, whereas they were aware that every year he gave increased encouragement to the social institutions, and aided the prosperity of this country. He had had the opportunity of observing his Royal Highness for many years, and it was quite remarkable to see what knowledge he possessed of almost every science in every department, and how he increased his enjoyment of everything that related to the fine arts, as well as to more practical pursuits. With regard to enjoyment, he remembered a great friend of his (Earl Granville's)—one of the best informed men in the House of Commons—telling him that his great love for reading, and his great pursuit of knowledge, had its origin in his poverty. He found reading so much cheaper than other amusements that he was driven into it, and not only had it taken him into the position he had attained, but it had given him the highest enjoyment, which no other pursuit afforded. The report alluded to the progress that had been made, but when it was considered that the metropolitan district contained three millions of inhabitants, a very small fraction of persons would be affected by the operations of the Society. Taking into consideration, however, the large number of persons who by their position were necessarily excluded from these examinations, and considering also the very natural reluctance of older men to subject themselves to attending examinations in competition with younger persons, they would not find the state of things nearly so discouraging as it appeared to be. He did not, at any rate, wish to discourage the older persons from devoting a great deal of time even to the elementary portions of education. Not long before his death, Lord Lyndhurst consulted Mr. Gladstone as to whether he was using the best Greek dictionary, as he was reading Homer, and derived great enjoyment from it. With regard to what was suggested as to female education, he could not but express his great pleasure at this portion of what the association had done. He thought it was highly encouraging to see that [the Princess of Wales had followed the example set to her by her illustrious mother and father-in-law, and had become the patroness of an Association such as this. The report made a touching appeal for help to so young a society and so useful an institution. He believed it to be unnecessary for him to say anything on the subject, because the fact that they were tending to stimulate education—that they were trying to urge young men to improve their prospects in this life, and, as he firmly believed, to fit them for another world—would be their strongest claim to assistance. He did not think Government could do much to aid this movement, but the principle of giving clerkships by examination certainly did exercise a valuable influence. In the department over which he had the honour to preside two candidates from the Society of Arts' Examinations had been successful, and in another depart-

ment there was a much larger number, and he was happy to state that every one of those persons was doing well, and some excellently well. Some difficulty had been raised against the system of competition; but he could vouch, from his own experience, that there was no comparison between the competitive and probationary systems. He might mention also that employers of labour attached great value to persons who had distinguished themselves in examinations of that kind. He concluded by expressing his hopes for the continued success of the Association. Archdeacon Utterson, in moving the publication of the report, recommended the system of examination as a means of inducing young persons to concentrate their attention on particular subjects. Sir Thos. Phillips seconded the resolution. On the motion of Mr. Powell, M.P., seconded by Mr. Shaw, the officers for the ensuing year were elected; and a vote of thanks to the chairman brought the proceedings to a close.

RICHMOND YOUNG MEN'S SOCIETY.—A most valuable encouragement has recently been given to this Society, by the kindness of Earl Russell in consenting to become its president. On Monday, the 16th January, a deputation of gentlemen connected with the Society, and consisting of the Rev. Mr. Ingram, the Rev. Mr. Webster, J. G. Bohn, Esq., W. J. Maxwell, Esq., H. Hill, Esq., C. Ellis, Esq., and others, waited upon Lord Russell, at his residence, Richmond-park, for the purpose of presenting him with an address of thanks. The deputation having been introduced by Mr. Bohn, Mr. Gouldsmith read the address, which was elegantly illuminated. In addition to a cordial expression of thanks, it briefly described the main objects of the Society, which are "the mental and spiritual improvement of its members by means of a library for circulation and reference, reading-rooms, classes for the study of the Scriptures, elocution, music, English and French literature, &c." and also paid a tribute to the eminent services of his lordship in the cause of social and political progress.—**EARL RUSSELL**, in reply, said "he was most happy to accept the presidency of the Society, and felt it an honour to be connected with so valuable an institution. It was a great motive with him, in undertaking this position, that the society regarded the religious interests of its members of paramount importance, and attached so much value to the circulation of a wholesome literature. It was also a source of great gratification to him that Richmond was likely to be benefited as Manchester and other towns had been, by the exertions of such a Society. He ventured to hope that the future labours of the particular institution represented by the deputation would be pregnant with the happiest results to this neighbourhood and the country at large." His lordship afterwards intimated his intention of appearing publicly in the capacity of president of the Society, at as early a date as should be found convenient. The fourteen years of the establishment of this Institution have witnessed a progressive increase in the number of its members (now scarcely fewer than 300), and a corresponding augmentation of its means.

ART SCHOOLS AND ART INSTRUCTION.

The following is the substance of the minute of the Committee of Council on Education, dated 9th February, presented to both Houses of Parliament by command of Her Majesty. It will be of interest to the Institutions in Union, as it opens up the means of aiding night classes for drawing, without requiring any connection with a School of Art:—

My Lords having given their attention to the report and resolutions of the select committee of the House of Commons on Schools of Art, to the suggestions made by individual members of the committee, to the evidence of the witnesses, and the letter of Mr. A. Baresford Hope, acting on behalf of certain art schools, as well as to

various memorials and documents which have been sent to the Science and Art Department from the local schools of art, observe that the resolutions of the Select Committee offer no recommendations respecting elementary instruction in drawing given in schools for the children of the labouring poor, or given to the masters and pupil teachers of such schools, or to adults taught in night classes, objects of the first importance which may be promoted independently of special Institutions constituted as Schools of Art.

All these objects having been matured by the Science and Art Department into a national system of art-instruction, have been supported by Parliament for several years, and have taken root as an effective and successful system which it is desirable should not be impaired, whatever changes it may be expedient to make in the administration of local Schools of Art proper.

The Science and Art Department has steadily borne in mind that national improvement in manufactures can only be secured by the existence of a healthy demand and supply of such manufactures, arising from the improved taste and knowledge of all classes of the community, and that this result could most effectually be obtained by placing the greatest variety of means of instruction within the reach of all as far as practicable. Elementary drawing is taught especially to children of the poor, and to adults in schools and Institutions which are not Schools of Art. Drawing, painting, and modelling are taught in schools of art; whilst fine examples of art-workmanship of all ages and countries and styles are exhibited for public instruction in a central museum which is open both day and night, under a more liberal system than exists, at present, in any other capital in Europe.

It has been the consistent aim of the Department so to regulate the expenditure of public money on these several means of instruction that, if it should be the pleasure of Parliament to reduce or withdraw its votes in any direction, the public might be induced to supply instruction in art by municipal or voluntary action.

The report of the Select Committee confirms generally the soundness and success of the department's policy, and suggests modifications which are calculated to extend the principles of self-reliance, and to simplify the relations between the Schools of Art and the Department. The principal recommendations of the report refer to local Schools of Art, in reference to which the committee recommend—(a) That local schools of art be left to establish themselves wherever they can take root, and to extend their operations to all classes of society, and to charge such fees as their managers may think suitable. (b) That no further grants be made in aid of buildings, renting, or repairing Schools of Art. (c) That no further grants be made in aid of purchasing examples to Schools of Art. (d) That it be a condition of Government aid, that a public examination of every aided School of Art be held annually, through the agency of its local committee, and that the results of such examination should be reported to the Department in such form as the Department may prescribe. (e) That fewer prizes and no medals should be given by the central Department, on local examinations of aided Schools of Art.

These suggestions clearly indicate the opinion of the select Committee to be that Schools of Art should chiefly rely on their own resources and local exertions, being relieved from any Government control, and free to work according to the wishes and peculiar wants of each locality. This view entirely accords with the policy of the Department, which has always aimed gradually to render the Schools of Art less and less dependent on direct state assistance, and to make them self-acting and supporting. In 1851 the Parliamentary votes paid direct to the local Schools of Art, amounted to £6,880 for 17 schools having 2,842 students, being an average cost of £2 8s. per student, whilst in 1863 the corresponding payments to the local Schools of Art amounted only to £4,005 for 90 schools, having 16,480 students, being an average of only

4s. 10d. per student. Had the Select Committee recommended a return to the system of payments on teachers' certificates the whole charge on the Department in respect of them would have been only £2,836. These payments are exclusive of the cost of the National Art Training School, annually amounting to £4,450, of payments on results for elementary teaching £1,104, on prizes £2,461, on prize-studentships £1,063, and on art pupil-teachers £1,961, objects which have exercised a most important but indirect influence on Schools of Art. The Department having thus succeeded in reducing the direct payments, the Select Committee has now recommended the abolition of most of the indirect sources of aid, and the conversion of all payments into one capitation grant to each school of art. There was a great advantage in this variety of aid, because such aid could be modified from time to time in any directions experience might suggest. The mode and extent of its application were under control and new applications of it could be introduced. My Lords consider that these various kinds of assistance and stimulus could not be wholly withdrawn without inflicting a serious blow on a system which by general consent at home, and especially abroad, is considered to have worked well.

The Select Committee having affirmed the public utility of Schools of Art, it must have been their opinion that these schools have so far established themselves in the country that they must have nearly reached the point of self-dependence, and would not be imperilled by the suggested changes. My Lords would themselves have hesitated to say that this point has altogether been reached at present, but they are not so convinced of the contrary as to assert that the modifications recommended by the Select Committee would be permanently injurious to the schools or might not be safely tried to a great extent.

My Lords entirely agree with the Select Committee in thinking that Schools of Art should be left to establish themselves wherever they can take root, and to charge such fees as their managers may think suitable. The obligation of teaching elementary drawing in poor schools or to artisans at 6d. a-week, as conditions of recognizing a School of Art, will therefore no longer remain in force; and the masters of the art schools will thus be relieved of the obligation of performing work which has been called unremunerative. A local School of Art, as distinguished from adult night classes for drawing, will hereafter be defined simply as an Institution which is applied exclusively to the teaching of art at all times, and not to other purposes. Every place will be the judge of its own wants, and the only condition for receiving any direct payments from the State will be that there must be night classes for artisans open three times a-week at fees within their reach, the amount being settled by the local committees, and that the teachers must have taken from the Department a certificate of competency either of the second or third grade. Mechanics' Institutes, Literary Institutions, and schools for general education will be free to establish night classes for adults to learn elementary drawing without incurring the expenses necessary for the special premises or outfit of a School of Art.

My Lords regret that the Select Committee recommended all aid to be withdrawn towards buildings for Schools of Art. The provision of a suitable building is the greatest of all difficulties in establishing such a school; the special requirements for proper lighting by day and night rooms for art instruction are rarely met with in existing structures, and it is generally necessary to construct rooms specially. Out of the 90 existing schools, very few indeed are quite suitable, and by far the cheapest are those in which a moderate aid from the Department has been obtained and the Department's experience has been followed in the plans. This aid has also been the means not only of eliciting local subscriptions to a much greater extent than would otherwise have been the case, but in some instances of causing buildings to be undertaken which

without such aid would not have been begun at all. It may also be observed that the legal obligations entered into by any place receiving a building grant afford a security for the permanence of Schools of Art which might otherwise be abandoned at a period of temporary depression. Schools of Art have memorialised their lordships against adopting this recommendation. My Lords feel bound, however, to adopt the recommendation of the Select Committee that all direct grants should be withdrawn in future; and they will promote the erection of suitable buildings by enabling masters of Schools of Art and local architects to visit the training school and profit by all the experience the Department possesses. No grants will be made in aid of renting or repairing any established School of Art, which must pay all charges for rent, taxes, and repairs.

In accordance with the recommendations of the Select Committee, no further grants will be made to Schools of Art as such in aid of purchasing examples of a high artistic character, but aid towards obtaining a few elementary examples to be used in the artisan night classes will be continued. Considering the loose and inaccurate style of drawing still prevailing and almost popular, my Lords question the policy of this recommendation, but they propose at least to give it a trial. The local Schools of Art will be free to select and use what examples they please, except only in the few instances of some descriptions of works to be sent up for the national competition.

All local examinations in art, both in Schools of Art and elsewhere, where elementary drawing is taught, except in training colleges, will be conducted, in future, as in schools of science, by local authorities and not by Government inspectors. No more local medals will be given in future by the Department, and the number of prizes of books and instruments will be reduced in accordance with the recommendations of the Select Committee.

With respect to the recommendation of the Select Committee that "payments to certificated art teachers should be so far assimilated to those made to teachers of science that a capitation payment should be made for every artisan student who has received 40 lessons within the year," my Lords have to remark, in the first place, that no capitation payments are or ever have been made to teachers of science, who are paid wholly on results after having given 40 lessons during the year; and in the second place, that no evidence was submitted to the Select Committee on the policy of applying a capitation grant for the instruction of artisans. A capitation grant on behalf of a school child may be defended on the ground that the child is unable itself to pay for its instruction. In night art-classes as well as in a School of Art the artisan must pay a fee for his instruction or he cannot obtain it, and his attendance is his own voluntary act for his own direct and immediate benefit. If the capitation were sufficiently high the artisan might be tempted by the remission of all fees, and perhaps even by receiving a share in the capitation grant, to record forty attendances unaccompanied by serious study. Any capitation grant, however low, becomes a premium to the artisan to pay less than he otherwise would, and is in opposition to a sound system which would rather aim to encourage him to pay the full price within his means. The point always to be borne in mind is, that if local Schools of Art are to take a permanent footing in this country, the work can only be accomplished by inducing those who derive benefit from them to support them adequately. A capitation grant would violate this principle and be fatal to self-support and voluntary exertion. The cost of any capitation grant would be great and beyond control. It may be inferred from certain documents that the Art masters would wish it to be about £2 a head. It will be obvious that the amount of capitation grant ought to be fixed, if at all, not with reference to the existing number of Schools of Art, and the number of artisans attending them at the present time, but with reference to any possible extension

of these numbers. The numbers of the industrial classes who might claim a capitation grant probably exceeds four millions. Although it is not likely that so large a number would be claimants for a capitation grant, still the numbers would probably be much too large to admit of any such amount of capitation grant as that suggested. A small capitation grant would not be worth all the trouble and the details of administration necessary. My Lords therefore arrive at the conclusion that they could not undertake the responsibility of recommending this mode of assistance to the consideration of Parliament. The proposed removal of the obligations to perform unremunerative work and of the restrictions as to examples, &c., places the art teachers in a better position than ordinary drawing masters. The art teachers are trained at the public cost, and are certificated as competent: they are relieved of the risk of finding suitable premises and costly examples; they may teach at any rate of fees, whilst pupils are attracted to them by Government examinations and prizes, National scholarships, and Free studentships. With advantages like these any direct payment from the State to the art master may be dispensed with. My Lords are clearly of opinion, that if any direct payments are to be made to Schools of Art at all, they must be of a character to be under strict control as to amount; that they must not create the expectation of vested rights, or prejudice the success of voluntary exertions, and that they must be capable of being easily modified and withdrawn as Parliament may desire.

My Lords consider that some direct payments may continue for the present to be made in respect of students trained locally as teachers, as national scholars, and as local prize students, and also in respect of making an annual report for the information of Parliament. Payments for affording elementary instruction to schoolmasters or pupil-teachers or to adults in night classes will be continued to Schools of Art if the Committee think fit to engage in this work.

As respects elementary instruction in drawing in schools for the poor, and in night classes for adults, my Lords do not consider that the objections against capitation payment in a School of Art apply to the children of the labouring poor in a national school. It is proposed to continue a low payment somewhat of the nature of a capitation payment on school children learning drawing, and to raise the present payment from 6d. to 1s. for each school child who passes an examination in elementary drawing. Graduated payments on results will continue in force. Aid in obtaining suitable examples of an elementary character will continue to be given as at present, as well as prizes to the children.

Payments and prizes for elementary instruction for pupil-teachers, schoolmasters, and adults taught in night classes will be continued, such payments being made only on results. Aid on elementary examples will continue to be given. And all teachers who have obtained the second grade certificate will be qualified to receive payments.

The local examinations in schools for the poor and night classes in Mechanics' Institutes and similar institutions will be conducted as in schools of Science by the local Committees, and not by inspectors, and the works will be sent up to the Department for examination. Elementary instruction in drawing will thus be put on a distinct basis of its own, and a separate vote will be proposed to Parliament for it. The managers of schools for the poor and of Mechanics' Institutes and other similar institutions will be able to take advantage of the government aid without having necessarily any connexion with a School of Art; but there will be no objection to any organization for such instruction and for examinations in connection with a School of Art, if the respective managers agree upon having them.

In future the Department will conduct all correspondence direct with the managers of Schools of Art, Mechanics' Institutes and other institutions, and schools for the labouring poor, and will make all payments to

them, and not to the masters as at present. The managers and the teachers will therefore be free to make their own arrangements for payment.

My Lords concur in the recommendations of the Select Committee that the National Art Training School should be maintained according to the evidence of all the witnesses, and propose that the national scholars chosen from local schools shall be increased in number.

In accordance with the recommendation by the Select Committee, there will be an annual national competition for prizes of books, instruments, and the like, among works produced both in night classes and in Schools of Art; and payments will be made to the managers of the schools or night classes from which the successful works have been sent. The national medallions will be discontinued, and a very few medals substituted for them. No School of Art will be obliged to send works to this competition; but if they elect to do so, they must in a part of the course follow certain prescribed examples, so as to subject the competition to an equal standard of judgment for the whole country. Artists will continue to be the judges of such works; but in cases where original designs for manufactures are sent, besides artists as judges, my Lords will consider the propriety of inviting the assistance of competent persons as representing the purchasers in the community.

My Lords will endeavour to render the collection of works of decorative art at South Kensington as useful as possible throughout the country, and with this object will revise the present regulations. They propose to relieve Schools of Art of all cost of transport, packing, and conducting the exhibitions, requiring only that suitable space be provided for the purpose by the locality at its own cost, and for a sufficient time to warrant the expense to the State.

The votes for the Museum at South Kensington, the Schools of Art, and for elementary instruction in drawing, will be kept distinct and laid before Parliament in greater detail than heretofore, and the cost of examples to be preserved in the Museum will be transferred to the estimate for the Museum.

Their Lordships think it right to observe that the cost of purchasing objects for the Museum is to be viewed not as an expenditure transferable to local Schools of Art, but is rather a national investment which has both an intrinsic value of its own, and one which even increases in value. This expenditure does not in any manner affect the amount of aid given to local Schools of Art which it is their Lordships' opinion should as far as possible have the character of voluntary and self-supporting institutions under local management, and always aim at that independence of State control which is so honourable a characteristic of the general feeling of this country.

The changes proposed will slightly diminish the total estimate for the Art Division of the Department in the present year, and if in the growth of the system any increase should take place in future years, it will probably be confined to the head of elementary instruction for the poor.

The schedule to the foregoing minute gives the payments on behalf of artisans and children of the labouring poor, proposed to be made by the Department in all cases to managers of schools and classes as follows:—

I.—To Schools of Art.

(a.) Five shillings for every artisan who pays fees for being taught in a night class held three times a week, and passes satisfactorily an annual examination in a given time, and a further sum of ten shillings for such artisan student if he submits for examination drawings executed by him during the previous year which are satisfactory.

(b.) Five pounds for free studentships will be allowed for every fifty artisans satisfactorily taught in night classes of Schools of Art.

(c.) Ten shillings for each artisan who submits for examination satisfactory works executed by him during

the year, eligible for national competition, and a further sum of ten shillings on behalf of each artisan student from whose works any are selected for national competition.

(d.) Five pounds for a national scholar, being an artisan or designer, admitted to the National Art Training School.

(e.) Ten pounds for every certificate taken by an art-teacher trained in the local school.

(f.) Ten pounds for the annual report, provided that artisan night classes are held, a free studentship obtained, and works sent to the national competition.

(g.) See also II.

II.—To Night Classes in Mechanics' Institutes and similar Associations, and National Schools, &c.

(a.) Five shillings for every artisan who pays fees for being taught in a night class held three times a week, and passes satisfactorily an annual examination of the second grade in a given time, and a further sum of ten shillings on such artisan student if he submits for examination drawings executed by him during the previous year which are satisfactory.

(b.) Ten shillings for each artisan who submits for examination satisfactory works executed by him during the year, eligible for national competition, and a further sum of ten shillings on behalf of each artisan student from whose works any are selected for national competition.

(c.) The teaching in night classes may be given in connexion with Schools of Art or not. Teachers must have taken second or third grade certificates.

III.—To Schools for the Labouring Poor.

(a.) One shilling for every child in a national or similar school taught drawing satisfactorily, with additional payments of two or three shillings for success. Managers of schools for the labouring poor are free to have the teaching of drawing given either in connexion with a School of Art, or by any teacher certificated in the second grade.

Managers of schools for the labouring poor and of night classes for artisans will be aided to the extent of 50 per cent. on examples for elementary drawing.

The above-mentioned payments are exclusive of prizes to be awarded to students themselves.

THE PATENT LAWS.

The following are the recommendations of the commissioners appointed to inquire into the working of the law relating to letters patent for inventions:—

"1. Your commissioners do not find that the present cost of obtaining letters patent is excessive, or the method of payment inconvenient; they do not therefore recommend any alteration of the present system on those points; but they think that patent fees should not be made to contribute to the general expenditure of the state until every reasonable requirement of the Patent Office has been satisfied. 2. They are unable to recommend a preliminary investigation into the merits of the invention for which a patent is claimed; but they advise that a careful inquiry be instituted under the direction of the law officers of the Crown as to whether there has been any previous documentary publication of the invention, either by grant of letters patent or otherwise; and if such publication have taken place, that the patent shall be refused. No evidence other than such documentary evidence should be admissible, and the reasons for the refusal to grant the patent should be certified by the law officers; an appeal from their decision should lie to the Lord Chancellor. 3. Your commissioners are of opinion that the present mode of trying the validity of patents is not conducted in a satisfactory manner. That such trials ought to take place before a judge sitting with the aid of scientific assessors, but without a jury, unless at the desire of both parties to the suit or action. That such assessors ought to be selected by the judge in each case, and the remuneration to be paid them be

included in the costs of the suit and action, and provided for in such manner as the judge shall direct. That no special judge be appointed for the trial of patent cases, but the judges of law and equity be empowered to make rules by which one court should sit for trial of patent cases exclusively. That on such trial the judge, if sitting without a jury, decide questions of fact as well as of law. 4. That the granting of licences to use patented inventions ought not to be made compulsory. 5. That patents ought not to be granted to importers of foreign inventions. 6. That in no case ought the term for which a patent is granted to be extended beyond the original period of 14 years. 7. That in all patents hereafter to be granted a proviso shall be inserted to the effect that the Crown shall have the power to use any invention therein patented without previous licence or consent of the patentee, subject to payment of a sum to be fixed by the Treasury. 8. While, in the judgment of the commissioners, the changes above suggested will do something to mitigate the inconveniences now generally complained of by the public as incident to the working of the patent law, it is their opinion that these inconveniences cannot be wholly removed. They are, in their belief, inherent in the nature of a patent law, and must be considered as the price which the public consents to pay for the existence of such a law.

(Signed) "STANLEY, OVERSTONE, W. EBLE, W. P. WOOD, H. M. CAIRNS, H. WADDINGTON, W. R. GROVE, W. E. FORSTER, WM. FAIRBAIRN."

DUBLIN INTERNATIONAL EXHIBITION.

The allotments of space to exhibitors in the United Kingdom have been issued, but, owing to the space demanded being seven times in excess of the whole quantity at the disposal of the Executive Committee, it has been necessary to refuse many applicants and considerably reduce the demands of others. The Corporation of the City of London, the National Gallery, the Royal Academy, and numerous private individuals, lend pictures for exhibition. There will be a very fine display of furniture, most of the principal London makers exhibiting. Glass and china will also be well represented. Nottingham and other manufacturing towns will make a collective display. The British colonies will be creditably represented. Nova Scotia will have an admirable collection, the legislature having voted a large sum for the purpose. Canada and some of the other North American colonies will also be represented; and Natal and Mauritius intend to exhibit. The foreign contributions will be varied and attractive. The Emperor of the French has promised to send Sevres china and other objects. Krupp, of Essen, will exhibit steel ordnance. A very fine collection of textiles is promised from Rhemish Prussia; lamps and bronzes from Stobwasser, of Berlin; pianos from Zurich, and other manufactures from Switzerland, as well as a good collection from Russia.

Fine Arts.

SOUTH KENSINGTON MUSEUM.—The Lords of the Committee of Council on Education have recently issued a minute, expressing their desire to obtain a design for the decoration of one of the large lunettes at the north end of the south court. The lunette is a semi-circle of eighteen feet radius, a strip of one foot six inches high being cut off the bottom by the skirting. The subject is to be an illustration (life-size) of workmanship in any decorative art or manufacture. Three artists will be invited to make suitable designs, for which the Department will pay £50 each. In addition to the artists to be named, artists of any country not specially invited can compete if they think fit to do so. Two sums of £50 and £25 will be paid respectively to the two artists, not named by the De-

partment, whose designs are chosen. The design ultimately adopted by the Department will be enlarged by students for execution in mosaic, life size, and the artist whose design is chosen for execution will be required to superintend the enlargement of the work and approve it, for which he will receive a further payment of £50. All the designs will be publicly exhibited. They are to be made to a prescribed scale, namely, within a lunette formed by the segment of a circle of one foot radius, cut off by a chord parallel to the diameter one inch above the diameter. Thus the segment will be of nearly two feet base, eleven inches high. The designs are to be sent in with a cipher, on or before the 15th June, 1865, addressed to the Secretary of the Science and Art Department, South Kensington, London, W. The names of the judges will be hereafter announced.

EXHIBITION OF DRAWINGS ON STAINED GLASS.—The valuable collection of drawings (above seven hundred), made by the late Mr. Charles Winston, will be exhibited next month, under the auspices of the Archaeological Institute, in the rooms of the Arundel Society. These drawings were made with the most scrupulous attention to accuracy of detail, truth of colour, and form. Doubtless such an exhibition will be very acceptable just now, as so much attention is being given to an art nearly lost. Some of Mr. Winston's friends and admirers are preparing to collect and publish, as a memorial of him, the papers on painted glass, &c., which he had communicated at various times to different societies of which he was a member; many of these have never before been published. The volume will be richly illustrated by many coloured plates from his original drawings, as well as wood engravings, which have been intrusted to Mr. Philip Delamotte, of King's College. This work will be published by Mr. Murray.

Commerce.

THE FRENCH TREATY AND ENGLISH SODA AND BLEACHING-POWDER.—The French Government have returned the following reply to representations which have been made to them, setting forth the injurious effect of the rate of duty leviable under the Anglo-French treaty, upon soda and bleaching-powder exported from this country into France:—"When in 1860 the import duties on the chemical productions in question were fixed at 18 per cent., and commencing from October the 1st, 1864, at 10 per cent. *ad valorem*, the French manufacturers felt considerable anxiety, which was subsequently justified by the great disparity between the cost of manufacture in England and in their own country; it was, indeed, only through the removal of the salt duty, and through strenuous exertions on their part, that they were enabled to sustain the competition of England. The difference between the price of coal in the two countries constitutes an advantage to the English manufacturers, 15 francs per ton on coal, or 60 francs per ton on soda ash, whilst the import duty is only 30 francs, or 41 francs, including the Excise duty. The cost of salt and of pyrites seems to be about the same in either country. But, apart from this, the documents published by the French Custom-house authorities show the exportation of sodas, not to mention 116 tons shipped to outports during the first three-quarters of this year, to have been unimportant, while, on the other hand, since the commencement of the present treaty, Great Britain has exported to France 3,190 tons of sulphate of soda, 1,983 tons of soda ash, and 2,586 tons of crystals of soda. Bleaching-powder, however, may possibly be in a better position to allow of an abatement in the import duty than soda-ash or crystals of soda, but it must be observed that in its manufacture, which is closely connected with that of soda, of which it utilises the principal residuary product, it is but reasonable to take into account the reductions on the last-named article. Besides, the importation of bleaching-powder, referred to by the petitioners, which

took place at the beginning of this year, was the result of an accidental state of affairs. At that period rags were exceedingly scarce, and large quantities of esparto grass and other similar materials were employed in England in the manufacture of paper, which considerably augmented the consumption of chemicals containing chlorine, and thus the price was raised to a point which permitted the French manufacturers to conclude some transactions, of a limited nature it is true, and which have entirely ceased since the month of August. Under these circumstances it has not been considered advisable to entertain the request of the Newcastle and Gateshead Chambers of Commerce."

RESIN IN FRANCE.—A new branch of industry is about to be commenced in the Morbihan, which it is expected will add considerably to the wealth of that province. The extraction of resin from the pine trees in the extensive forest of Lanvaux is to be carried on there on a grand scale. For that purpose several cargoes of earthenware cups have been imported at Vannes. The apparatus is extremely simple; each cup resembles a small flower-pot, with the difference that one of the sides is concave, so that it can be fixed against the tree to be tapped, so as to facilitate the flow of the liquid when the tree is pierced.

AMERICAN HOPS.—Twenty-four years ago the United States produced only 6,000 bales of hops. Ten years later, in 1849, the production had increased to 17,000 bales. The next decade shows a larger increase than in any other agricultural product, the growth of 1859 reaching 55,000 bales. The crop of 1862 was estimated at 80,000 bales, a maximum which has not since been attained. The yield of 1863 was estimated at 65,000 bales, while that of 1864 is stated at 45,000 bales.

PATENT LAWS.—The following remarks, extracted from the judgment of the Lord Chancellor, in the case of *Simpson v. Holliday*, merit the attention of inventors:—"Cases of this nature frequently give rise to complaints of the state of the law. It is, therefore, right to point out how entirely the plaintiff's failure has arisen from not availing himself of the salutary provisions of the existing statutes. The provisional specification proves that a valuable discovery had been partially made, but not matured, and that the true conditions on which it might become an invention of practical utility had not been ascertained. Six months are allowed by the law for maturing the invention and accurately ascertaining and stating it; but in this case there does not appear to have been any attempt by the patentee to improve his knowledge; for the complete specification is a mere repetition of the provisional. Lastly, the inefficiency of the cold process, and the dangerous language of the specification must have been known long prior to this suit, and yet there was no attempt to remove the objection, as might easily have been done by a disclaimer under the statutes."

MARINE RAILWAY ROUND THE FALLS OF NIAGARA.—At a recent meeting of the Detroit Board of Trade, the subject of a marine railway round Niagara Falls, for the transportation of vessels with their cargoes from Lake Erie to Lake Ontario, and *vice versa*, was brought up for consideration. The subject was suggested by a letter from Mr. Horace H. Day, who states that last summer he caused the proper surveys and plans to be made for a marine railway around the American side of Niagara Falls, adapted for transporting loaded vessels of all kinds of such tonnage as can be profitably employed in lake trade. This he proposes should be built as a substitute for a canal, and at a cost of about one-third. He asserts that it is practicable to pass vessels floating in the moveable locks from Lewiston to the Niagara River, above the falls, in less than two hours, with entire safety to ship and cargo, while the time of passing the necessary locks of a canal is estimated at from twelve to sixteen hours each way. This railway should (he says) have six rails of suitable construction, and with proper turn-outs, and different-sized locks for different-sized vessels. These locks are proposed to be wood and iron, with gates at each end.

Colonies.

NEW ZEALAND.—The coal obtained from Kawakawa mine, at the Bay of Islands, province of Auckland, is said to be of a first-rate character. To raise steam by means of the best coal from Newcastle the period of 1 hour and 45 minutes is required, while it has been found that for Kawakawa coal no more than 1 hour and 5 minutes is requisite. The province now possesses coal mines in various parts of the country.—The Auckland Gas Works are in a forward state. A capacious tank, for receiving the gas holder, is nearly completed; the diameter of the tank is 54 feet, the depth being 16 feet. A well, calculated to yield between 4,000 and 5,000 gallons in the 24 hours, has been sunk, after some considerable difficulty, experienced through the fact of the penetration being entirely through rock, to a depth of upwards of 200 feet. It has not been drilled in the usual manner with a screw, but with a jumper, which has been attached in lengths of wrought iron tubing, the same as a boring rod. The rock through which this well has been sunk consists of alternate strata of slate and freestone.—The bridge over the Waikonaiti stream is completed. It is of wood, and is about 400 feet in length, and 20 feet wide. The opening of the bridge is hailed by the inhabitants of the district as a great boon, many of them having suffered serious inconvenience from the impediments which previously existed to travelling.

COTTON AND SUGAR IN QUEENSLAND.—Notwithstanding the unfavourable circumstances which operated against the raising of cotton during last year, the crop bids fair to exceed that of all previous seasons, and it was expected that upwards of one hundred bales would be shipped. Three gins, driven by steam power, have been constantly at work. A portion of the cotton was grown on the plantation of the Manchester Cotton Company; another portion at Nerang Creek, by a private company, and the remainder is the produce of various farms in the neighbourhood of Brisbane and Ipswich. That from the plantation of the Manchester Cotton Company is of fine quality, and although portions of it have been somewhat stained and injured by wet and unfavourable weather, it is considered to be worth 5s. 6d. per lb. in the present state of the market. In addition to the above, there are ten bales of ginned cotton, from the plantation of the Cabulture Cotton Company. These facts speak for themselves. That such satisfactory results have been attained during the unfavourable circumstances of the past season, show that cotton can be grown there with every prospect of success. Messrs. Board and Sons have produced some very fine sugar-cane, and a sample of sugar manufactured by Mr. Buhot, prize essayist on sugar culture, at Maryborough, from canes grown by Mr. Eaton there, promises to be good, dry, and of a rich yellow description—worth there about £40 per ton. The means of manufacture were of an exceedingly simple and rough kind—an old patent mangle being the crusher, and a saucepan the boiler.

Obituary.

THE DUKE OF NORTHUMBERLAND died at Alnwick Castle on Sunday, the 12th instant. He was the youngest son of Hugh, the second duke, and was born in 1792. He married, in 1842, Lady Eleanor, eldest daughter of the Marquis of Westminster. In early life he entered the navy, and obtained the rank of post-captain in 1815. He saw, during ten years, considerable active service in the Mediterranean, but after obtaining his rank as captain he retired. In 1816 he was created a peer by the title of Baron Prudhoe, and sat in the House of Lords as such until he succeeded his brother, the third duke, in February, 1847. After leaving the navy, he devoted himself to travel, and with his friend Sir Gardner Wilkinson,

passed some years in Egypt and the Holy Land. In 1852, on the Earl of Derby being called upon to form an administration, he accepted the office of First Lord of the Admiralty. He was president of the Royal Institution of Great Britain, and of various other societies. Within the last few years he expended above £500,000 in improving the dwellings of the labourers on his estates. He was elected a member of the Society of Arts in 1814.

SIR JOHN HARE, F.G.S., F.S.A., a well-known citizen of Bristol, died recently at his French residence of Chateau d'Hardelot, near Boulogne. He was born in 1784, and was the head of the firm of John Hare and Co., floor-cloth manufacturers. He was chiefly notable for his connexion with the anti-slavery movement. In the heat of the discussions on this subject there was an election for Bristol, the candidates being Mr. James Evan Baillie, a whig, who supported the West Indian interest, and Mr. Edward Protheroe, a whig, who supported emancipation. Sir John Hare took an active part on behalf of Mr. Protheroe, and barely escaped with his life at one of the party banquets at Bristol, the Baillieites making a dead set at the Protheroites. Sir John was knighted in 1840, on the presentation of a congratulatory address from the city of Bristol on her Majesty's marriage. He was the owner of the ship *Cambria*, which is said to have saved the crew and the passengers (including the 31st Regiment) when the *Kent*, East Indiaman, was destroyed by fire in the Bay of Biscay. He was elected a member of the Society of Arts in 1861.

JOSEPH LIES, a Belgian painter, died recently of consumption, at the age of forty-three years. On the very day of his decease he finished a picture which he had in hand. Lies was of a truly artistic nature, learned, gentle, and sympathetic, and was endowed with great intelligence and a kind heart. He was much esteemed by the elder painter Leys, to whose instruction and influence he was much indebted in the earlier portion of his career. A portrait of one of Ley's children by Lies is considered the best work of this artist.

Notes.

BRITISH HOROLOGICAL INSTITUTE.—A lecture on "The Greenwich System of Time Signals," illustrated with diagrams, by William Ellis, Esq., F.R.A.S., of the Royal Observatory, Greenwich, is to be delivered at the house of the Society of Arts, on Friday, 24th February, at 8.30 p.m., the Right Hon. the Lord Mayor in the chair. Free admission to members of the Society of Arts.

WEST LONDON EXHIBITION.—A public meeting was held in the St. John's school-rooms, John-street, Tottenham-court-road, on Wednesday, the 8th inst., for the purpose of affording information respecting the industrial exhibition which has been set on foot in the western district of the metropolis, and adopting measures in furtherance of it. Deputy-Judge Payne occupied the chair, and was supported by Mr. J. A. Nicholay, Mr. T. H. Filmer, Messrs. G. Corbett and D. P. Foxwell, and a deputation from the Central Committee. The industrial exhibition movement in the west of London originated with the committee of the All Souls Working Men's Club. Ten members of the Working Men's Club Exhibitors' Committee, and an equal number elected from a public meeting, were soon constituted a central committee, whilst to secure an efficient representation of the surrounding districts, numerous public meetings have since been held, at which district committees have been formed, each of which appoints a delegate, who, with its chairman and secretary, become members of the central committee. With the view of obtaining a suitable building, it was determined to rent the site of the late Portman Barracks, until the end of June, for a sum of £600. Upon this it is proposed to erect a building, which will give ample accommodation. It is proposed to open the exhibition from the middle of April to the end of June. The com-

mittee calculate that to accomplish these objects they will require a guarantee fund of £2,000, over £1,200 of which has already been guaranteed.

EXHIBITIONS.—The Lucknow Exhibition was opened on the 24th December. All the capital for the great exhibition in Bombay has been subscribed, and all the shares have been taken up. The *Gazette* says:—"One great difficulty connected with the undertaking is occasioned by the want of available house-room in Bombay. The city is likely to get a name for very cold hospitality, if, after inviting ten thousand strangers to visit the exhibition, it denies them the ordinary accommodation of board and lodging. Yet there is certainly no place of shelter for a multitude of visitors in a city in which European residents often have to search vainly for weeks together for houses (or rather barns) in which to rest their heads. The projectors of the exhibition must therefore provide an hotel for their expected guests; and we hear that, as the time is too short for masonry work, it is their intention to have a large iron and terra-cotta building erected near the exhibition."

WHAT IS AN INCH OF RAIN?—The last weekly return of the Registrar-General gives the following interesting information in respect to rainfall:—"Rain fell in London to the amount of 0.43 inches, which is equivalent to 43 tons of rain per acre. The rainfall during last week varied from 30 tons per acre in Edinburgh to 215 tons per acre in Glasgow. An English acre consists of 6,272,640 square inches; and an inch deep of rain on an acre yields 6,272,640 cubic inches of water, which at 277.274 cubic inches to the gallon makes 22,622.5 gallons; and, as a gallon of distilled water weighs 10lb., the rainfall on an acre is 226,225lb. avoirdupois; but 2,240lb. are a ton, and consequently an inch deep of rain weighs 100.993 tons, or nearly 101 tons per acre. For every 100th of an inch a ton of water falls per acre." If any agriculturist were to try the experiment of distributing artificially that which nature so bountifully supplies, he would soon feel inclined to "rest and be thankful."

MEETINGS FOR THE ENSUING WEEK.

- MON. ... Society of Arts, 8. Cantor Lectures. Professor Ansted F.R.S., "On the Applications of Geology to the Arts and Manufactures." (Lecture III.)
British Architects, 8.
Medical, 8.
R. United Service Inst., 8½. Commander P. H. Colomb, R.N., "On Modern Naval Tactics."
- TUES. ... Civil Engineers, 8. Discussion upon Mr. England's Paper on "Giffard's Injector."
Statistical, 8. 1. Dr. Wm. Farr, "On Infant Mortality, and on alleged Inaccuracies of the Census." 2. Dr. Hyde Clarke, "On the supposed Decrease of the Turks."
Pathological, 8.
Ethnological, 8. 1. Mr. John Crawford, "On the History of Cannibalism in reference to Social Progress." 2. Mr. Travers, "On the Destruction of the Aborigines of Chatham Island by a Maori Invasion."
Royal Inst., 3. Prof. Tyndall, F.R.S., "On Electricity."
- WED. ... Society of Arts, 8. Mr. George R. Burnell, F.G.S., "On the Municipal Organisation of Paris, especially with reference to Public Works."
Geological, 8. 1. Prof. R. Harkness, "On the Lower Silurian Rocks of the South-East of Cumberland, and the North-East of Westmoreland." 2. Mr. R. Spruce, "Note on the Volcanic Tufa of Latacunga, at the foot of Cotopaxi." Communicated by Sir R. Murchison. 3. Dr. H. P. Blackmore, "On a Discovery of Flint Implements in the Drift at Milford Hill, Salisbury." Communicated by Mr. John Evans.
Archaeological Assoc., 8½.
- THURS. ... Royal Inst., 3. Prof. Tyndall, F.R.S., "On Electricity."
Antiquaries, 8.
Royal, 8½.
Philosophical Club, 6.
- FRI. ... Royal United Service Institution, 3. Capt. H. Schaw, R.E., "The Employment of Electricity in Military Operations."
Royal Inst., 8. Mr. John Evans, "On the Forgery of Antiquities."
- SAT. ... R. Botanic, 8½.
Royal Inst., 3. (No Lecture.)

PARLIAMENTARY PAPERS.

SESSIONAL PRINTED PAPERS.

Delivered during the Vacation 1864.

- Par.
Numb.
- 66 (vi.) Trade and Navigation—Accounts.
490. Poor Removal—Return.
501. Tea, Sugar, &c.—Returns.
496. Dockyards—Second Report (corrected).

Patents.

From Commissioners of Patents Journal, February 10th.

GRANTS OF PROVISIONAL PROTECTION.

- Air, impregnating with vapours from tar, &c., for hygienic or therapeutic purposes—112—A. J. Sax.
Alcohol, rectification of—250—W. E. Newton.
Animals, bits for—66—L. Weber.
Animals, oil cake and food for—292—G. J. Vertue.
Arm chair, portable folding—280—W. E. Gedge.
Boats, apparatus for lowering—210—T. Steel.
Buildings, roofs or coverings for—129—F. C. Fourgeau.
Carriages, instantaneously releasing horses from—2925—G. Prioleau.
Carriage step arrangements—182—H. A. Dobson.
Cast iron, treating articles of—192—P. M. Parsons.
Chimney-pots—284—G. Carter.
China, &c., placing in receptacles for firing—276—J. Meakin.
Clothes fastener—268—J. W. Gill.
Coal dust, &c., machinery for compressing—220—W. Smith.
Coal gas, purification of—226—A. A. Croll.
Corkscrews—283—J. Roper.
Cotton gins—248—B. Dobson and W. Slater.
Drilling machines, &c., section and arrangement of—341—J. Combe.
Electric pile—206—J. Rovère and H. A. B. Huguet.
Electric telegraph wires, laying, &c.—269—R. A. Brocman.
Fibrous materials, apparatus for washing—251—J. Petrie, jun.
Fibrous materials, preparation of—158—T. Mayor.
Fibrous materials, washing and drying—281—J. and W. McNaught.
Fibrous substances, expressing oil or grease from—261—W. Teall and A. Naylor.
Fire-arms—188—J. Snider, jun.
Fire-arms, breech-loading—124—W. Ansell.
Flax, &c., breaking and scutching—277—J. Gray.

- Fruit, means of preserving—267—G. Haseldine.
Furniture, rendering soundless—196—A. Drevelle.
Grinding corn, feeding apparatus of mills for—205—R. R. Riches and C. J. Watts.
Hot pressing, folding fabrics on to cardboards for—278—A. Freeman.
Hydraulic steering apparatus and rudder break—116—A. and E. Paul.
Hydro-carbon fluids, lanterns for burning—256—A. S. Macrae.
Ice safes—230—C. Falck.
Iron and steel, manufacture of—229—J. G. Wilhans.
Kempy wool and hair, colouring—227—H. W. Ripley.
Lamps, shades or globes for—266—R. A. Brocman.
Lifts, mode of working hydraulic—180—W. Clay.
Locomotion on land—271—M. Henry.
Malae, &c., manufacturing cyrrup and sugar from—246—G. Haseldine.
Manure, manufacture of—202—B. King.
Metal for roofing, preparing and fixing plates of—232—G. Dibley.
Metals, anti-corrosive varnish for protecting—259—J. Melznes.
Mixed fabrics, separating wool from—3235—S. Saville.
Mortar mills—262—J. Raines.
Motive power, &c.—55—G. B. Galloway.
New thread for weaving, manufacture of—212—R. A. Brocman.
Oils obtained from tar, treatment of—244—J. H. Johnson.
Paper, apparatus for drying—198—A. Sheldon.
Photographs, giving permanence to and ornamenting—72—E. Pettitt.
Photographs, producing and finishing—56—B. W. Bentley and W. H. Bailey.
Pipes, sockets for—285—G. H. Pierce.
Ploughs—34—J. Skelton.
Puddling furnaces, lining the sides and bottoms of—224—R. Munhet.
Pumps—198—J. H. Wilson.
Railroads, permanent ways for—164—J. G. Wilson.
Railway carriages, adjusting the weight of—216—O. Gessell.
Railways, permanent way of—164—R. Mallet.
Railways, permanent way of—275—E. P. Colquhoun and J. P. Ferris.
Revolving motion, intermittent and continuous—272—T. Hall and S. Bower.
Saddle trees, manufacture of—J. Southall, jun., and H. Southall.
Scent, apparatus for containing and dispersing—194—E. Atkinson.
Shells (explosive), construction of—136—J. B. Cotter.
Ships, cleansing the bottoms of, at sea—225—J. Harrison.
Ships, &c., coating the bottoms and sides of—264—J. Moysey.
Ships, forts, &c., armour-plated—286—J. Hughes.
Ships' legs and sounding machines—233—J. E. Massey.
Spring mattresses and palanquins—24—D. Verlochio.
Steam boilers, preventing deposits in—218—C. D. Abel.
Steam generators—243—J. I. Wivill.
Steam joints, &c., packing for—217—W. Paton.
Submarine cables, working of—166—S. F. Van Cheste.
Tanning hides and skins—270—W. H. Cox.
Tar oils, treatment of—245—A. H. Brando.
Theodolites—70—B. P. Bidder.
Throistle spinning frames—236—C. D. Abel.
Venetian blinds, apparatus for painting—170—D. Munro & T. Wright.
Vessels, machinery for propelling—228—J. Hamilton, jun.
Vulcanising compounds and vulcanised fabrics—176—B. F. Stevens.
Wall fruit trees, frost screen awnings and netting for protecting—267—C. A. Wheeler.
Wires ropes, apparatus for relieving the strain on—262—J. Gibson.
Woollen cloth, &c., facing—178—J. Snell and W. Benton.

THE Journal of the Society of Arts, AND OF THE INSTITUTIONS IN UNION.

111TH SESSION.]

FRIDAY, FEBRUARY 24, 1865.

[No. 640. VOL. XIII.]

TABLE OF CONTENTS.

Announcements by the Council:—Ordinary Meetings—Cantor Lectures—Institution received in Union ... Page 237	Proceedings of Institutions:—Leeds Mechanics' Institute ... 249 The Royal Scottish Society of Arts ... 250 Fine Arts:—Exhibitions—The Cariatides of Salonica—Royal Academy of Belgium ... 251 Manufactures:—Exhibition—Manchester Workmen's Exhibition—Midland Counties Industrial Exhibition—Standard of Electrical Resistance ... 251 Commerces:—Tobacco—Alloys of Silver. 252 Colonies:—Tasmanian Products for the	New Zealand Exhibition—Tasmanian Agricultural Show—New South Wales: Agriculture ... 252 Obituary:—Mr. Samuel Gregson, M.P. 252 Notes:—Exhibitions: Protection to Inventions—Royal School of Naval Architecture and Marine Engineering—Rain—Tea-making ... 253 Meetings for the Ensuing Week ... 253 Parliamentary Reports ... 254 Patents ... 254 Registered Designs... ... 254
Proceedings of the Society:—Cantor Lectures: Second Course: 3rd Lecture—Twelfth Ordinary Meeting—"On the Municipal Organisation of Paris, particularly with regard to the Public Works, by George R. Burnell, Esq., F.G.S. ... 237 Discussion ... 245		

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MARCH 1.—"On the Means employed in taking Fish, especially with reference to Submarine Illumination." By F. W. CAMPIN, Esq.

MARCH 8.—"On Cotton Gins." By ZERAH COLBURN, Esq.

CANTOR LECTURES.

The Second Course of Cantor Lectures, the subject being "The Applications of Geology to the Arts and Manufactures," by Professor D. T. ANSTED, M.A., F.R.S., is now being delivered on Monday evenings, at Eight o'clock, as follows:—

FEB. 27TH.—LECTURE 4.—On Mineral Materials (*continued*): Building Stones and Slates, and their Relative Value under given Circumstances of Exposure, and on Methods of Quarrying.

MARCH 6TH.—LECTURE 5.—On Stratified Deposits of Minerals as Coal and Iron Ore, usually obtained by Mining Operations, and on Mining Methods for such Deposits.

MARCH 13TH.—LECTURE 6.—On Metalliferous Veins or Lodes and their Contents, and on the Extraction of Metalliferous Minerals from Lodes.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

INSTITUTION.

The following Institution has been received into Union since the last announcement:—

Huddersfield Mechanics' Institution.

Proceedings of the Society.

CANTOR LECTURES.

SECOND COURSE.—THIRD LECTURE.—MONDAY, FEB. 20.

MINERALS OBTAINED FROM SUPERFICIAL DEPOSITS.

Professor ANSTED stated that he next proposed to speak of mineral substances used for special practical purposes.

Of these there are several classes:—(1.) Sands used in manufacture, or for casting. (2.) Sands and gravels consisting partly of gold, diamonds, tin ore, &c. (3.) Plastic clays. (4.) Limestones used in construction after burning. (5.) Building stones. (6.) Coal, iron stone, etc., forming strata in the earth. (7.) Ores in mineral veins. In his address this evening he meant to allude to the first four of these classes. *Silica sand* is valuable in glass making. Samples free from foreign substances are obtained from rocks of various geological ages; among others, from the beds at the bottom of the tertiary series at Alum Bay, Isle of Wight, where the quality is very good, and adapted for the best flint glass. Others are from the Hastings sands; from the lower greensand at Aylesbury; from the sands of Reigate, and from near Falmouth harbour and other places on the coast of Cornwall. A peculiar kind of sand is obtained not far from Bath, and is known as Bath stone. It is used for polishing. It consists chiefly of the cases of infusorial animalcules accumulated in beds, and consisting of almost pure silica in a fine state of division. Tripoli, or rotten stone, is somewhat similar, and is obtained from limestone of the carboniferous series. The polishing powder of Bilin, near Berlin, is of the same nature, and has the same origin. Sands and gravels often contain fragments of such metals and minerals as can be broken or ground up into minute particles, and are not readily decomposed by weathering. These include diamonds, amber, iron ore, tin ore, and gold. Some are rare, others common. Some occupy a small space in the sand or gravel that contains them, but others form the principal part of such material. Diamond washings are carried on in India and Brazil. The process of exploring is simple enough; the implement being a pick-axe, with which men dig into every promising spot. The diamond matrix is first picked out from the loose pebbles, and the selected mass spread out on a flat surface, where it can be examined grain by grain. The earth sought for is a red ochrey clay, containing oxide of iron; but diamonds are also found in the loose mud. Alluvial ores may be included in one general description. Gold, and the oxides of tin and iron, are found in important quantities, and the treatment of tin ore and gold requires separate notice. Stream tin occurs in Cornwall, but the chief supply is from the Island of Banca, in the Eastern Archipelago. Gold is chiefly obtained from sands and gravels derived from some parent rock or vein, but detached, and rarely affording a clue to its origin. Such sands are found in Europe, in certain parts of Siberia, in Africa, especially on the west coast, in Brazil, Mexico, California, Colombia, Australia, and New Zealand. Gold is found in river beds, and

in ancient detritus. The Banks of the Rhine and Danube, and the sands of the Tagas, are auriferous. The washing of gold alluvia is a very simple matter. A wooden bowl, shaken artificially with water, separates the heavier from the lighter mud. The latter is floated off until a residuum of gold is obtained. Each country and river bed has its own indications. In some the gold is found in dust, or spangles floated away by water. In others the particles are grains, and resist the current. Sometimes heavier grains or nuggets are found; native platinum and rare metals often occur with them. These deposits may be brought down from great distances, where the gold-bearing veins crop out. More usually the auriferous mud is but the washing of auriferous sands and gravels long since accumulated. Thus, in the Rhine, the mud is derived from a sand bank above the place of working. The gold is found in flakes or spangles so exceedingly minute and thin that it needs fourteen hundred to weight a single grain. A cubic yard of the mud will contain from five to forty thousand of these spangles. Compared with Siberia and South America, these Rhine sands are very poor, the Siberian gravels yielding five times, and those of Chili ten times as much. The Siberian gravels are coarse, being composed of shingle of fragments of the adjacent rock. They occur along the eastern flank of the Ural chain, both in the north and south valleys, and in those which run transversely. The former are generally the richer. The gold alluvia of Siberia are of definite geological age, and belong to the boulder gravels deposited by ice during the glacial period. The Brazil auriferous deposit is called *Cascalho*. It is an indurated soil broken up with pick-axes, and afterwards exposed to a current of water, or a loose gravelly stratum of rounded pebbles. It rests on granite, and is covered by earthy matter. Its thickness is very variable. The Californian gravels consist of coarse and small stones, mixed with mud and fine sands. Some of these are the actual beds of the existing streams; but the great deposits of such material have been already made, and are not now in progress. In Australia the gold-bearing gravels are deep, and seem to carry gold throughout. Shafts sunk through them to a couple of hundred yards reach gold, and the heaviest and largest lumps of gold have been found at the lowest depths. The most important recent discoveries of rich gold alluvia are those of British Columbia, New Zealand, and Nova Scotia. In all these gold has been found by prospecting, the first discovery being accidental. In the rivers or gullies opening out from the mountains, there are sands and gravels containing the gold in minute specks, visible grains, and now and then great nuggets. These latter are the temptation to the adventurous miner, and, at rare intervals, several of unusual size are found in the same locality. As a specimen was mentioned a case in the gravels of British Columbia. Five partners commenced working at Cariboo, in 1861. During the first three days they obtained little. On the fourth day they raised 4 ozs.; on the fifth day, 10 ozs.; and on the sixth, 41 ozs. of gold. The yield went on increasing until it reached 357 ozs. in one day, and the last day's work resulted in the obtaining of 469 ozs. The total value of the gold raised was upwards of £20,000, and the dimensions of the claim were only 80 feet by 25 feet superficial. The economical working of auriferous deposits is a matter of practical importance. The methods adopted are nearly the same as those in use in Cornwall for reducing tin ore. The cost of crushing gold quartz would, no doubt, be somewhat greater than in Cornwall, but the operation may be profitable; even when the percentage of the precious metal is extremely small, provided the quantity of ore is sufficiently large. Gold gravels sometimes contain the following crystals and native metals:—Sapphire, topaz, spinel-ruby, zircon, tourmaline, garnets, olivine, platinum, palladium, osmium, stream tin, diamonds, and quartz. All the productive streams for tin ore are in the valleys on the southern side of the Cornish peninsula,

although most of the richest veins of such ore are on the northern side. Here we have evidence of a drift from the north conveying the tin; and a similar conclusion must be drawn from the facts concerning the principal gold drifts north of a certain line in Europe and Asia. But how is it that such a drift, produced by a submarine current or wave flooding the land, can have deposited the stream ores? This involves a consideration of the mode in which the granite districts of Cornwall have been decomposed. Those who know the infinite multitude of small veins and branches carrying tin ore that traverse the easily decomposed granites of St. Austell and its neighbourhood, will not doubt that if a body of water were now to rush across that part of our island, the decomposed granite would be removed, the broken up quartz strings containing tin would be rolled into pebbles, and the tin-bearing pebbles would be separated. Owing to their greater specific weight these pebbles would first come to rest, and if once drifted into hollows would not easily be removed. On the other hand, the lighter material would be much further transported. It is difficult to form an idea of the original extent of the accumulations of tin stone gravels that have been the object of incessant exploration for several thousand years in Cornwall. There are perpetual indications of former workings, at intervals, along the whole distance from Dartmoor to the Land's End, and the ground has often been turned over twice or thrice. But there is still sufficient unmoved ground to illustrate the general geological facts. The stream works mark great changes in level as well as causes of drift, now unknown in the district. The upper limit of the tin ground in Pentuan was 46 feet below the level of high water at spring tides and 30 feet below the level of low water, but it was once covered with vegetable soil, and the land at that time possessed human inhabitants. In many other instances, as well as this, there is unmistakable evidence of depression, to the extent of at least fifty feet within the human period, without the smallest evidence of any great earthquake disturbance or any change in the dip of the rocks. It is also certain that the depression has been general over an extensive area, and that it has been very gradual. On the other hand, there is equally good evidence in Cornwall itself and in the adjacent county of Devon, that in many places there has been local elevation, to an extent even much greater than this depression, and also within the human period. It must be remembered that, while sometimes the valuable minerals, being heavy, are left behind and deposited at the bottom; in others they are lighter than other stones, floated onwards, and caught up accidentally, or left permanently at the top. This is the case with amber—the ancient resinous excretion of certain extinct pines. On the shores of the Baltic, pits are occasionally sunk through loose sand to a hundred feet, with a view of reaching the fragments of this substance in the uppermost of the regular strata below the sand. Elsewhere the amber is floated or drifted to shore during storms, and is then picked up before it is caught and covered up by the blown sands. The lecturer then proceeded to the consideration of plastic materials. Four varieties of clay are used in the arts, each having its own peculiar properties, and each available for some special purpose. They are brick clay, fire clay, pipe clay, and pottery or porcelain clay. Brick clays are widely spread, and few countries are without some varieties. In England they are common, often forming very thick and extensive beds. The clays of any locality are almost always used for brick-making for common purposes in the district where they occur; for clay will not readily bear the cost of conveyance. The finer kinds are different, being conveyed in a prepared state to the place of manufacture. Brick clays consist of a coarse and irregular admixture of pure clay—with sand, lime, iron, carbon, mineral alkalis, and a host of impurities. The admixture with sand is essential; and the proportion of sand in clay, as well as the composition of clay, admit of great variety. The

clay must be free from large stones; but the admixture of a large percentage of silica-sand is not incompatible with the formation of an excellent brick. The number of stock bricks annually manufactured and used in England must exceed one thousand million; and brick-pits have been opened in the neighbourhood of every town in which dressed stone is more expensive than brick. Generally, iron, lime, potash, or soda are unfavourable signs in a brick clay; for they would cause the brick to run in the furnace. By burning clay loses the capacity of mixing with water, and its plasticity. It becomes hard, resists weathering; and if iron has been present, it converts the dull brown of the clay into a bright red. To make a good brick, the clay must be freed from pebbles and ground up into a uniform mass. In preparing for manufacture, it must be mixed with coarse sharp sand. In a good brick clay there should not be more than 2 per cent. of lime or potash. Fire-clay is a variety that bears intense heat without melting; and fire-bricks should bear exposure in the interior of furnaces. The alkalies, alkaline earths, and iron-oxide, which would help to flux it, are absent. Fire-clays often contain carbon, and some are the floors beneath seams of coal. Of other clays some are adapted for coarse pottery; others for finer kinds of ware; others for the whitest and best kinds. There are also pipe clays, and, lastly, *Ka-o-lin*, found not only in China but in Cornwall and West Devon, in Central France, and in Northern Germany. Pottery clays are more plastic than brick clays, and resist the most intense heat of the furnace. They contract with much irregularity, and the iron they contain communicates a colour, varying in intensity with the quantity of the metal. Pottery clay is used for some manufactures little superior to ordinary brick or tile, and others hardly inferior to porcelain. No precise line can be drawn concerning them, nor does analysis strictly define their value. The raw material results from a separation of coarse and impure parts of common clay by water and exposure to weather. Pipe clay is a variety containing an excess of silica and very little iron. China clay is formed by a natural or artificial washing from the decomposed felspar of certain kinds of granite. It is of a loose earthy texture, and light (ag. 2.21 to 2.26). The composition varies from different localities, the limits being wide. The preparation of china clay for the potteries is simple, and consists in washing the decomposed rock in a succession of tanks, so that the particles of quartz, mica, and other minerals, may either fall from the water in which they were mechanically suspended, or be carried forwards by the velocity of the stream; while the fine particles, consisting of the remains of the decomposed felspar are allowed to settle quietly in tanks prepared for them. The decomposition of the granite leaves the quartz in stones, which are generally crystalline and angular. These are got rid of in a catch-pit, through which the whole is carried along by a current of water. The operation of washing has been performed naturally, both in Cornwall and Devonshire. The decomposed granite has been washed through a valley, the coarse particles of quartz being left in the upper part of the valley, and the particles of fine sand brought to the lower part. More than 10,000 tons of the finer and three times as much of the commoner kinds of clay are annually made use of in the Staffordshire potteries. Cements and plasters were next noticed. Their use is very ancient. They are of various kinds, and available under very different circumstances. The most common and familiar is *mortar*. It is obtained by calcining limestone, and converting it into quicklime. After calcining quicklime is a greyish substance, which absorbs water with the evolution of much heat, and falls into a fine powder, which is next mixed with two or three times its own weight of sharp sand to form mortar. In time a film of silicate of lime is formed round each grain of sand, and the whole mass, and the stones between which it is placed, become closely adhered. As there are different kinds of limestone, there result limes of

different quality and properties. These require special treatment. Marbles or chalk make a rich lime, setting firmly only in dry air, while the very impure limestones with which clay is largely mixed, result in hydraulic limes, which set more or less rapidly in moist air, or even under water. Some impure limestones are used in the manufacture of cements. Sometimes, by the admixture of certain substances (as *pozzuolana*) with rich limes instead of sand, hydraulic limes are produced. It is not difficult to trace the changes that take place in the conversion of limestones into cement. A layer of mortar, not too thick, placed between bricks or stone and kept in dry air, dries gradually, and holds stones together with extraordinary tenacity. But this is a work of years, and sometimes even centuries must run out before the extreme of hardness is attained. It is not unusual to find imperfectly-hardened mortar in very old constructions. Limestone is widely distributed, and almost every variety can be burnt for lime. In the manufacture of good common mortar pure limestones and all of fair ordinary quality are available; but in using them attention must be given to their composition, and even texture. The hardest make the fattest lime, other things being the same; but each variety yields lime of different quality—distinct in colour, in weight, and in the greediness with which it absorbs water. The mode of calcination varies, but after burning limestones, the quicklime is lighter than the ordinary stone, and differs from it essentially. Limestones that contain from one to six per cent. of foreign substances, such as silica, alumina, magnesia, iron, &c., yield rich limes. Poor limes are obtained from limestones in which foreign substances, such as sand, carbonate of magnesia, oxides of iron, and manganese, are present to the extent of from 15 to 30 per cent. These increase little in bulk on slacking, do not set under water, and are soluble, like the rich limes, except that they leave an earthy residuum. Between eminently rich and eminently poor limes there is, of course, every gradation, and great importance is attributed to the state of the limestones and the nature of the foreign substances present. Fossiliferous limestones make bad mortar, as the slacking is irregular. Limestones containing much silica swell in setting, and dislocate masonry executed with them. Where alumina is in excess the lime is apt to shrink and crack. Where carbonate of magnesia is combined with carbonate of lime, as in the magnesian limestones, the original bulk is well retained. Hydraulic limes are of very great value in construction. They are either obtained naturally from the burning of certain varieties of calcareous rock, or are manufactured artificially by mixing limestones with foreign ingredients, or by combining quicklime with foreign materials. Roman cement, Portland cement, Parker's cement, and many others, are varieties of artificial cement. Nodules and argillaceous bands in clay deposits yield the largest quantity and best quality of limestones for burning into hydraulic lime. The limestone is argillaceous and combined with other impurities, among which iron oxide and carbon are very frequent. It is generally considered that from 15 to 25 per cent. of a limestone should consist of silicate of alumina, in order that it may burn into a good hydraulic lime. Such limestone is got from the *septaria* or calcareous nodules, in the London clay at Sheppey, the Kimmeridge clay at Weymouth, the Oxford clay, &c. Similar material occurs in bands in the lias at Whitby, and elsewhere. Good hydraulic cement is made by mixing the river mud of calcareous and clayey districts with chalk. Admixtures of burnt clay as well as *pozzuolano* and *trass*, have also been found to render fat limes hydraulic. Portland cement, largely manufactured at the mouth of the Thames, is a mixture of chalk and river mud. Roman cement is formed of the nodules found near Harwich. In making cements the materials are pounded together under water, and afterwards dried and burnt. The cement is largely used for artificial stone, made up with broken and crushed brick, mixed with about ten or twelve times its weight of broken stones and pebbles. Portland

and Roman cements make an excellent concrete. Portland is in this respect stronger than the older manufactured Roman cement, but for many purposes there is nothing to choose between them. Gypsum (sulphate of lime) is collected and burnt, like common limestone, to manufacture a plaster or cement. The calcining of gypsum does not involve decomposition, but the water of solidification being driven off, there is left only a soft white powder called plaster of Paris; when this is united with water the water is reabsorbed, and the mass becomes first plastic and then solid. When mixed with weak glue instead of water, plaster of Paris becomes converted into *stucco*, a material also very largely used. When thrown into a vessel containing a saturated solution of alum, borax, or sulphate of potash, rebaked, once more powdered, and then moistened with a solution of alum, a hard plaster is obtained that takes a high polish. This plaster is called Keene's cement if made with alum, Parian with borax, and Martin's with pearlsh. *Pozzuolano* is a volcanic earth of a reddish colour, originally found in the vicinity of Pozzuoli, not far from Naples. Similar material has since been obtained from extinct volcanic districts, especially in central France, near Andernach, on the Rhine, and even near Edinburgh. When used instead of sand in mixing with limes, these minerals render all limes hydraulic, and have been used in this way from time immemorial with great success. Coal-cinders and slags also hasten the absorption of the moisture, and facilitate the setting of the limes with which they are used. Artificial pozzuolans are sometimes manufactured. Besides cements and terra cottas, used as artificial stones, many methods of imitating stone have been adopted. One of these, introduced some years ago by Mr. Frederic Ransome, deserves notice. It consisted of sand moulded with fluid silicate of soda, obtained by exposing flints in a steam boiler to the action of caustic alkali, at high temperature. At first Mr. Ransome supposed that by mixing sand and stone with the fluid silicate into a paste and exposing them to the air they would become solid. But stones thus made soon disintegrated. He then subjected them to the action of heat in a kiln, and found that at a bright red heat the silicate became an insoluble glass, unaffected by exposure to the air, and not cracking on exposure to frost. Stone thus made might be so porous as to filter, or so compact as to yield a material equal to Craigleith stone. Rubs and whetstones, garden vases, balusters, and various architectural features often constructed of terra cotta were thus produced, of superior quality and great durability. The stone thus made was found to become unweighty, owing to an efflorescence of sulphate of soda, and it was difficult to avoid disagreeable markings. The moulding of Ransome's artificial stone is easy and perfect, the shrinkage in the kiln extremely small. When finished it can be cut with the chisel. Its power of resistance to transverse strains exceeds that of excellent sandstones used for building, and is three times as great as the best limestones. To crushing weights its resistance is also remarkable. A two-inch cube sustained twenty-one tons. Ransome's "patent siliceous stone" was, however, too expensive to come into use on a large scale; and the ingenious inventor found a much cheaper and more satisfactory result by making stones and sand into a paste with the fluid silicate in the usual way, and then fixing the form instantaneously by dipping it into a solution of chloride of calcium, and producing a hard stone without drying or burning. It is difficult to form an idea of the rapidity of the process and the perfect result without seeing the experiment tried. The term concrete is generally applied to a species of rough masonry, consisting of gravel or broken stone mixed with lime, the lime being slacked upon, and in immediate contact with the gravel. The main uses of concretes are to distribute the weight of heavy constructions, and for backing coursed masonry where the walls are required to be of great thickness. Good concretes should set rapidly and completely, for to have any value all work in which this

material is used, needs to be performed quickly; and therefore either hydraulic limes or mixtures are necessary. The former should always be used when they can be obtained. But though hydraulic lime is desirable, the quantity used should not be in excess. Some care in selecting the rough stones and caution in not making the concrete till the lime is already converted into moriar are essential. The rapidity of setting may be varied by admixture of different material. Artificial blocks of concrete are made. They require to be constructed with great care, of the best materials, and carefully rammed. If dried too rapidly they are apt to crack. The blocks are admirable when successful, but mischievous if carelessly constructed. Bituminous cements are used for street pavements to replace large flags. In our own country, where we have abundant supplies of natural flagstones, they are little thought of. In France they are extensively adopted. The materials for these pavements are of two kinds—one nearly pure, the other a natural mixture of bitumen and sand or carbonate of lime. Asphalt is the technical name for the bitumens commonly obtained for pavements, and they are abundant in France, at Seyssel, and elsewhere. The best asphalt is black, brilliant, and hard at ordinary temperature. It softens in the sun. It should be free from sulphate of iron, and from sulphur in any form. When used it requires to be mixed with mineral pitch in a boiling state, and then formed into a cement, a little quicklime being added while the bitumen is boiling. There are many other applications and contrivances requiring geological knowledge to make use of them to the greatest advantage, and a vast variety of cases in which some acquaintance with the nature, history, and origin of rocks, and some idea of their metamorphoses and of their associations, will greatly help the practical man to obtain the material he desires.

TWELFTH ORDINARY MEETING.

Wednesday, February 22nd, 1865; William Hawes, Esq., Chairman of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Giles, Francis, 42, Blomfield-road, Maida-hill, W.
 Phillips, Thomas H., 10, College-crescent, Finchley-road, N.W.
 Savile, Edward B., 30, St. George's-road, Pimlico, S.W.
 Spriggs, William, 10, York-row, Kennington-road, S.
 Templetown, Major-General Viscount, C.B., Government House, Devonport.
 Walker, Micajah Hilditch, 13, St. Swithin's-lane, E.C.
 Warden, J. William, Warwick Cottage, Park-village East, N.W.
 Yardley, Vincent, 3, Thorney-street, Bloomsbury, W.C.

The following candidates were balloted for and duly elected members of the Society:—

Edwards, Henry, 58, Berkeley-square, W.
 Lambert, Charles, 3, Queen-street-place, E.C.
 Runtz, John, Burlington-house, Stoke Newington, N.
 Sanders, Samuel, 22, Sussex-gardens, Hyde-park, W.

The Paper read was—

ON THE MUNICIPAL ORGANISATION OF PARIS, PARTICULARLY WITH REGARD TO THE PUBLIC WORKS.

By GEORGE R. BURNELL, Esq., F.G.S.

It seems that, at the present day, the results that have been obtained by the organisation of the service of public works in the neighbouring capital, have dazzled the public to such an extent that it would not be surprising were an attempt made to introduce some imitation of that system into our own country. Paris has been transformed with almost fairy-like rapidity; it has been improved in its hygienic and its general character; it has

ally the city of pleasure, and the abode of intellect; public buildings of a fine monumter have arisen on every side; and at the service of the city, in so far as regards the life, has been largely and well cared for. ons have been opened, markets laid out, ic schools, churches, hospitals built; and and places of public amusement have been a degree of luxury of which we in e no conception. The results that have aded the Imperial Government of France been such as to cause both surprise and but I think that they are the results of a ould prove eminently a failure if applied in ntry; and as I flatter myself that I know the innermost details of the administration, I have thought that it might afford you sion were I to give you an account of the ganisation of Paris. There is much to be hat is passing amongst our neighbours, no : is also much to be avoided. It should be o learn all that they do that is worthy of order to place the administration of our is sound a basis as possible, after allowing t circumstances of the social organisation ntries.

things that strike the inquirer in the muni- ation of Paris, are—1st. That the capital the great cities of France constitute ex- be general law of *communes* that prevails in , and are administered in fact by what is *de bon plaisir*; and 2nd, that the “*régime*” is carried into execution by the instru- the organisation that previously existed. other cities of France, the prefects have very the *maires* and the municipal councils, which cted by the public, have, in reality, the un- rol of the funds raised from their fellow- Paris, in Lyons, and Marseilles, however, of the department have a more direct action, *les municipaux* are nominated at the choice of ; the *conseils* have, in the latter case, only a voice, which is easily controlled; the initiative vement comes from the prefect, who is all Of course, the prefect is obliged to carry out that he may form by the aid of the sub- *ployés* of the administration; and he is re- r the acts that he thinks proper to adopt, to ibunal of public opinion, which may be con- e represented by the semblance of the muni- l that authorizes, or not, the measures for o effect the resolutions of the prefect. But of control is very illusory, and it in nowise t the resources of the towns should be laid g to the wants of the population, or even ac- their means of supporting the charges the involve. Hitherto, it is true, no incon- but very little, has been found to arise from because, in the first place, there had grown in of Paris, Lyons, and Marseilles, in the course state of things that made any change a change ter; and, in the second place, because the hese cities are all of them high-minded men, rged views, and men who could well under- wants of the population whose welfare was their care. But what would be the ultimate ch a system, when the directing hand and empire was withdrawn? It is impossible to o high terms of the attention with which of the Parisian public, for instance, is con- he Government is literally there a visible to interpose between the consumer and the nd it makes, as the French people themselves *is et le beau temps*” in affairs which we leave of a real Providence, and try to shelter our- t as best we may. As far as they have gone,

the results of the system applied by our neighbours have been satisfactory, and France has increased in splendour and in real comfort in a degree which passes belief; the worst of this system is that it depends upon the lives and the intellects of the men who carry it into effect, and it is always subject to the errors that they may commit in their appreciation of the wants of the community.

But it is hardly the place here to indulge in abstract theories of government, and our business is more directly concerned with the measures adopted in Paris to carry out the immense improvements of that city. As was said, the system of government consists in, first, a prefect of the *département de la Seine*, who is a senator, and is named directly by the government; second, in a *conseil municipal*, consisting of sixty members, under the actual presidency of M. Dumas, the chemist and senator; third, of the different members of the administration, that is divided into a number of services, all of which it will not be necessary to notice upon the present occasion, as they are connected with the duties of the prefect that concern other functions besides the execution of public works. The prefect, in fact, represents the town in all that concerns the action of the government, and in all legal proceedings that may be undertaken for the defence of the interests of the municipality. He is charged with the execution of the police, conjointly with the prefect of that department; with raising the taxes and the execution of the conscription, with the service of the national guard, with the administration of the hospitals, the public assistance, the public education, and, in general, with all that relates to the government of the town. In this he is assisted by the *maires* and *adjoints* of the different arrondissements of Paris, who are also nominated by the crown, but in nowise subject to the election of those they rule. As the division of Paris into *arrondissements* and *quartiers* will very frequently come under notice in the sequel, it may be as well to say here that the city comprises twenty arrondissements, each of which has a *maire* and his *adjoint*, and is further subdivided into four quarters in each arrondissement. As the duties that are fulfilled by the *maires* and *adjoints* are exclusively confined to their magisterial functions, excepting in so far as they prepare the lists of the electors, there is not much inconvenience found to arise from their not being themselves elected; but, as will be seen in the sequel, there are grave objections to the municipal council being nominated, and holding their office at the will of the Emperor.

When, under this system, it is determined to execute a great public work, the course adopted is as follows:—The minister in whose functions the building enters (for in France the Minister of the State, the Minister of Public Works, the Minister of Worship, the Minister of War, have to do with as many of the buildings of Paris as the Prefect of the Seine) causes his employés to study the project, make the preliminary estimates, attend the inquiry that is held into the necessity for the execution of the work, and then presents his estimate, and all the documents connected with the inquiry, to the Chambers, in cases where the national funds are concerned, or to the conseil municipal when it is only a question of the funds of the locality. In Paris, the course is for the prefect to transact this business with the chiefs of the department of the *Voirie*, at this time under the direction of M.M. Tronchon and Deschamps, who are specially charged with the service of the setting out and regulating the streets of the city; but in every case the initiative proceeds from the prefect, who lays out the new lines of streets according to his own ideas upon the subject, and who is alone responsible for their direction to the Emperor. The project is then submitted to the Emperor in council, who decides whether it is of a nature to require the application of the law of public utility. The council of state orders an inquiry into this branch of the project, and, after hearing the various parties affected, it generally decides upon the question in favour of the prefect's design, and issues a decree to that effect. The project is then brought before

the conseil municipal, who decide upon the opportuneness of the execution and have to provide the sums of money that are required. The deliberation upon the project thus presented by the prefect to the municipal council is a mere *pro-forma* piece of business; almost invariably the decision of the council is that the work shall proceed, and then the orders are given to mark out the ground, and to proceed to ascertain the indemnity that is due to the proprietors who are turned out. This is an operation that is done at once, after due notice has been given; but the purchase of the land goes on after the construction of the new street has been decided on, let the estimates be ever so much exceeded. Upon the completion of the formalities, the prefect takes possession of the ground, and he either yields it to the "*Compagnie concessionnaire*," with the understanding that they will pay for the sewerage and water supply, the works for leading the gas to the public lamps, the execution of the roadway and footpaths, and the construction of the houses according to a plan determined upon; or he proceeds to the execution of these works by his own agents, and he, of course, receives the proceeds of the sale of the land that is reserved for building purposes. The latter course was adopted in the commencement of the great works of improvement in Paris; the former seems now the favourite with the prefect, as it leaves the municipality free to employ its credit and pecuniary resources, wherever he may think most desirable.

The execution of the works is divided into several departments, which consist of, 1st, the *Voirie*; 2nd, the *service des eaux et égouts*; 3rd, the *service du pavé*; 4th, the *service des promenades et des plantations*; 5th, the *service des travaux d'architecture*; 6th, the superintendent *des logements insalubres*; 7th, the *service des Ingénieurs des Ponts-et-Chaussées*; and 8th, the *service de la Carrières*.

The first of these comprehends all that relates to the plan of Paris, and to the proposed rectifications thereof. It embraces the setting out of the new streets; the fixing of the lines that are allowed to prevail; the projections on the public way; the numbering of the houses, the acquisition of buildings that are acquired by means of expropriation; sales and exchanges of land, &c. There are employed in this branch of the administration, in addition to the two gentlemen already named, seven surveyors, or *géomètres*; nine surveyors, who are charged with the topographical works; four chiefs of sections; and a countless number of subordinates, who are charged with filling up the details of the service. As Paris is now undergoing the process of being surveyed thoroughly, the number of *employés* in this department is very considerably above the average; but the numbers given may be taken as representing the normal composition of this branch. There are, in addition to it, twenty architects *voyers*, and twenty assistants, or two to each *arrondissement*, who have, in their functions, the observance of the laws that regulate party walls, and the numerous cases that continually arise with respect to the right of air, ventilation, and light, and to the right of support by the neighbouring property, that are always the source of complicated action in the interior of great towns. It is this branch of the service, as was said before, that the prefect consults in preference to the rest, for all that relates to the improvement of the town.

The services of the *eaux et égouts*, of the pavement, and of the promenades and public parks, are discharged by engineers of the Ponts-et-Chaussées, or of the state, who are specially detached from the ordinary service, and are allowed to enter into the employment of the city of Paris, whilst they retain their rank and privileges as members of that body. I think it necessary to dwell a little upon this point, because an imaginary distinction has been sometimes drawn between the town engineers and the engineers of the Imperial Government. All the engineers of Paris are members of the Corps Impérial des Ponts-et-Chaussées, whilst the works of the Louvre, which in a recent discussion before the Committee of the House of Commons were especially alluded to, are all

under the direction of M. Lefuel, who is an architect, and who is responsible alone for the success of them.

However, the three services named are united under the control of, at present, M. Michal, *Inspecteur des Ponts-et-Chaussées*, who has the general supervision, and regulates, as the last appeal, the various departments. He has under him, M. Belgrand, *ingénieur en chef de 1re classe*, who is charged with the *service des eaux et des égouts*, or in fact who takes the management of all that relates to the underground works of Paris. Then M. Homberg, *ingénieur en chef de 1re classe*, and M. Rozat de Mandres, *ingénieur en chef*, are charged with the superintendence of the paving, roadway, and footpaths, or everything on the surface of the ground; and M. Alphand, *ingénieur en chef de 1re classe*, is charged with the plantations, seats, sheds, lamps, and generally with everything *above ground*; so that these four gentlemen have very distinct provinces, and yet they are all of them subject to the control of M. Michal, who has the title of "Director of Public Works." M. Michal receives from the prefect, after the formalities of the inquiry into the expediency of the proposed lines of communication and the reference of them to the municipal council, have been fulfilled, the indications of the direction that the lines are to follow; and at the same time, the plan indicating the exact line of the properties that the city intends to buy. He then consults the engineers of the various branches of his service, and they prepare in concert a project for the sewers, the water supply, the gas piping, and the plantations; they prepare estimates and designs for the work, which are submitted to the approval of the prefect; and, if approved of by him, are at once executed. The principles adopted in these cases are to shorten as much as possible the distance between the extreme points to be connected, and to regulate the level; and it must be confessed that in the new streets and boulevards lately formed in Paris, this has been carried out with very little attention to economy in the laying out the lines, or in the levels given to them; but there are occasions when it is necessary to respect a public monument, or to preserve a certain gradient in order to accommodate a sewer, that may give rise to some deviations from the strict rule thus laid down. The engineers are, it must be added, directly interested in carrying out the works in the best manner, for they are charged with their maintenance, and their working afterwards; and as the city exercises a vigilant control over the sums allotted to this branch of the service, the engineers are kept thereby constantly on the stretch.

The bureaux that are immediately under the orders of M. Michal are not so numerously constituted as those of his subordinates, for he has only a general supervision over the works, and the engineers of the various departments prepare all the details of the execution; he has, therefore, principally to do with the accounts, and with the transmission of the orders of the prefect. In M. Belgrand's office there are three *ingénieurs ordinaires de 1re classe*, who are charged with the superintendence of the works that are in process of execution, and one other engineer who is charged with the construction and maintenance of the steam engines that are employed for raising the water; the laying the new pipes that are from time to time required is performed by the *ingénieurs* charged with the roadway, but under the orders of M. Belgrand, and they also exercise a control over the sewers, which come under that gentleman's direction, both for their construction and subsequent working and cleansing. As the gas pipes are laid in the soil, it follows that they also come under the province of M. Belgrand, who regulates everything that is concerned with what the French call the "*canalisation*," or the pipes that serve to lead the gas to the places of consumption; the quality of the gas, and the manner in which it is to be burnt, form, however, part of the functions of M. Alphand, the engineer of the promenades and public plantations, and he is assisted by a host of inspectors, *verificateurs*, superintendents, &c., who are charged with the details of the private lighting. The details

of the *service des eaux et égouts* give rise to the nomination of a great number of employés, amongst whom the inspector de l'assainissement has a staff of seven assistants to superintend the communication of the houses with the drains or sewers; an inspector for the preservation of the hydraulic works that are connected with the distribution of that fluid in the fountains, the street plugs, and the pipes; an inspector who regulates the supply that takes place in the public offices and the departments of the state; eleven persons are employed in the office of the engineer charged with raising the water; twenty-eight persons are employed to receive complaints and reclamations, and to give the temporary orders for repairs of the pipes that are in communication with the private houses; 105 persons who are charged with opening and shutting off the water from the various places of distribution; and finally fourteen persons who are charged with the superintendence of the various reservoirs. The city of Paris, it is to be observed, undertakes the supply of the water that is consumed in that town, and it is now energetically at work to improve both the quantity and quality of the sources it resorts to; in the meantime it delivers the water to a company, which undertakes the works that are required by the subscribers for water, and accounts to the town for the payment of them. The company is paid for its intervention in the matter by an allowance which it retains upon the amount of the sums it accounts to the city for. The distribution is on the constant delivery principle, but it leaves a great deal to be desired on the score of height; indeed the tenure of house property in Paris is in fact opposed to the profuse use of water we are accustomed to in England, and the supply may be said to be more municipal than it is domestic. It serves to wash the streets and to feed the monumental fountains more than it serves the household wants of the inhabitants, who, by the way, have learnt to pass over the deficiency of many things that in England are almost necessities of life. There is a strict relation between the services of water and sewers which in Paris has received a good solution, so far as the removal of the refuse from the streets is concerned; but the whole of this subject is so complicated, and it would lead to details of such length, that I must reserve them for another occasion. I may here mention that the city of Paris has treated for the supply of gas with a single company, on very favourable terms for both that company and itself. The affairs of the company are at present under the management of M. Gayfier, an *ingénieur en chef des Ponts-et-Chaussées*, and of M. Camus, *ingénieur ordinaire*, of the same body.

The service of the "parvé" is arranged in the following manner:—M. Hombert, the *ingénieur en chef*, has under his orders five *ingénieurs ordinaires*, and they have the control of a certain number of *inspecteurs*, usually about two for each *arrondissement*, a number of *conducteurs* and *piqueurs*, about four for each *arrondissement*, and a number of *cantonniers*, about forty for each *arrondissement*. M. Hombert is charged with the superintendence of the parts of the town that were included within the limits of old Paris, but when the limits of the town were carried back to the fortification, the paving of the districts thus included was entrusted to M. Rozat de Mandres, who has four *ingénieurs ordinaires* under his orders, with the usual number of *inspecteurs*, *conducteurs*, *piqueurs*, and *cantonniers*. These gentlemen are charged with everything connected with the level of the streets, both longitudinal and transverse; they arrange the fall of the channels and the points where the water is to be delivered and to be conducted to the sewers; they have the choice of the material that is to be used, either paving or macadam, and they fix the manner in which it is to be swept and cleansed; they execute the borders, and they have a control over the execution of the footpaths that are under the special care of the householders, unless the city thinks proper to plant them, when they pass under the control of M. Alphand. In Paris the materials used for the roadways are the grès or sandstones of

Fontainebleau, the porphyry of Belgium, the quartz rocks of various localities, the meulrières of the Paris basin, and the bituminous rocks of the subcretaceous formations of Beyssac, Neufchâtel, &c.; for the footpaths, they principally use asphalt, porphyry, and grès. The streets of Paris are models of cleanliness, and they may well bear comparison with those of London, or of any Dutch town, being managed upon a uniform principle, which our streets are deficient in. The gutters are carefully washed twice a day, and everything is removed from them before the inhabitants are abroad; and this is the more remarkable, because all the Paris houses are constructed without anything that corresponds with the dust bins of London, so that the Parisians are obliged to deposit everything in the shape of rubbish in the public streets. The engineer of the égouts, in fact, complains that his branch of the service is unfairly charged with the removal of much refuse that ought to be carried away on the surface; but this is a minor evil, which is amply repaid by the cleanliness and the good state of the roadways. Perhaps the street paving may be rather in a worse state than that of London is generally; but that is owing to the great expense of the materials employed in Paris; at any rate they never in that city expose their horses to the cruel task of wearing down the stones of their macadam, a system that prevails to a fearful extent, with loss to the parishes, be it observed, too, in our city that boasts so much of its civilization. In Paris the footpaths are, as was said before, under the special control of the householders, who can of course pave them in any way that they think proper; except in the new streets, where the city has executed them simultaneously with the roadways, and where the houses are made liable to a payment for their repair.

The bureau of M. Alphand, *ingénieur en chef* of the promenades and the public plantations, is composed of two *ingénieurs ordinaires* and a great number of *inspecteurs*, *conducteurs*, *piqueurs*, and *cantonniers*; there are also two architects, two *sous-inspecteurs*, one *inspecteur vérificateur*, and a host of clerks. The attributions of the office are the superintendence of the planting of trees upon the boulevards; the maintenance of the public parks; the establishment and maintenance of the public fountains; the decoration and the placing of the public lamps; the arrangement of the market places and the standing booths for public conveyances, advertisements, &c., in so far as they are unconnected with the building; in fact, the execution of everything that is concerned with the upper part of the public ways. In the discharge of these duties M. Alphand is assisted by the *ingénieurs ordinaires* of the *voies publiques*, but as much as possible the services are kept distinct.

The *service des travaux d'architecture* is an important branch of the administration, but it does not exercise much influence upon the lines, or directions, of communication, excepting in so far as they may interfere with the existence of monuments of great artistic and national value; and it is for this reason, principally, that the advice of the architects is taken. Under general circumstances, the architect's business is confined to executing the public buildings on the spots that are designated for them by the prefect, and they have to prepare their plans, in conformity with the instructions they may receive from him, and in accordance with the limits of expense that he may judge advisable. At present, the *service des architectes* is under the immediate presidency of M. Baltard, who has under him a *chef de bureau*, and a body of architects and inspectors charged with the maintenance of the Hotel de Ville and the various offices of the municipality. There are four architects-in-chief; one of whom has the direction of the buildings that are connected with the maintenance of public peace and the administration of justice; another, the building and maintenance of the places connected with public education; another, the places connected with commerce and the administration of the municipal laws and funds, such as the mairies,

tribunals of commerce, octrois, &c.; and the fourth, the superintendence of the religious structures. They are assisted by four *contrôleurs* and about 15 local architects, and two local architects are also named to superintend the departmental buildings; they have, as is usual in the French administrations, numerous subordinates, and there is quite an army of architects that is charged with the construction of new buildings; the number of these is not less than 38 at the present time, and it is calculated that the town has not less than 250 architects, conducteurs, piqueurs, and superintendents in its employment—the greater part being permanently engaged.

The superintendence of lodgings constitutes but a small branch of the administration of Paris, and it does not come into play at all in the improvements that have lately been carried on in that city; so that it will suffice merely to mention, in passing, that this object forms one of those that seriously occupy the attention of the prefect and of the municipal council. The works that form part of the attributions of the *ingénieurs des Ponts-et-Chaussées*, more directly concern the inhabitants of Paris, because they often blend themselves with the works executed by the engineers of the same body detached for the service of the town. Generally speaking the works that are required to connect the capital with other countries, and with the chief places of the several departments, the lines of internal navigation and the railways, fall under the care of the *ingénieurs des Ponts-et-Chaussées*; and we therefore find that the service of the Seine is organised in several bureaux, that is to say, the ordinary service, the service of the navigation, the service of repairing and maintaining the bridges, the service of the superintendence of railways. In this number are included about eight *ingénieurs-en-chef*, and about twenty-four *ingénieurs ordinaires*, who discharge duties that are very variable, and are rather indefinite in their nature, because they somewhat interfere with the duties of their colleagues; however, although the engineers of the state are under the immediate control of the minister of public works, they are, nevertheless, to a great extent, subject to the Prefect of the Seine, whose consent is necessary for any great operations that they may be called upon to perform. The same thing may be said of the service of the engineers who are charged with the superintendence of the works that are required for the consolidation of the quarries under Paris; these are composed of the engineer-in-chief of the mining engineers and two *ingénieurs ordinaires* of the same body, and their duties consist in the superintendence of the catacombs and the foundations of the public buildings. It is found necessary to organize a special service charged with this duty, which the prefect is obliged to consult whenever a new line of communication is to be established; but it is only as a precaution, and to ensure the safety of the buildings about to be erected. All the last-named branches of the administration only have the right to interfere with the prefect when his measures are likely to trouble the public convenience or security; and therefore they are only mentioned incidentally on the present occasion.

But it remains for us to ascertain how the prefect manages to provide funds for the total change that he is effecting in the plan of Paris, and in the improvements there carrying out under his energetic management. In the first place, the revenues of the town are of themselves very large, and they have been pledged long since to meet such of the expenses as are authorised by the government; and in the second place, the city of Paris has entered upon the abuse of its credit, by the creation of a species of floating debt, that I think will end in bankruptcy. The yearly receipts of the town of Paris are (or were last year) 155,590,040 francs, or £6,228,600 nearly, which are raised from a population of not more than 1,687,841; and this, it must be understood, only represents the sums that the inhabitants pay for their local taxation, for the government taxes, that are levied directly from the payer, are quoted at the sum of 83,411,718 francs, or the addi-

tional sum of about £1,885,468. This sum of about six and a quarter millions would amount to an annual payment of about £3 15s. per head of the population, and it cannot be a matter of surprise that the expense of living in Paris is becoming rapidly unbearable. The incidence of the taxation is no doubt dignified by reason of its indirectness, but this only makes it more heavily felt by those who do consume the articles taxed. A man pays in Paris according to his consumption, not according to his means; and thus the rich man escapes contributing to the state. The poor man is forced to pay more in proportion than his neighbour. Of course Englishmen have nothing to do with the manner in which the French may levy the revenue that they may require, but it is right to call attention to the radical unfairness of the system, when so many people here are clamouring for the introduction of a similar one amongst ourselves. As it is, however, the rate of local taxation may be taken at nearly 60 per cent. on the rental of the inhabitants of Paris, including, however, all the relief of the poor, the expenses of the hospitals, the schools, &c., which with us are left to the care and charity of private individuals.

But it is to the creation of a description of municipal floating debt that the most impartial people look with the greatest dread. The city of Paris, even now, has a funded debt that gives rise to the payment of 18,428,746 frs., to defray the interest, and 10,314,892 frs., for the sinking fund, or nearly a million a year is thus absorbed out of the 64 millions raised by the town. This is not all, however. The prefect has been allowed to issue obligations in the name of the city, and for the *caisse des travaux de Paris*, to the extent of 80 millions of francs, or for £3,400,000; and, if reports are to be credited, so far from his being contented with that enormous sum, he has extended it to the amount of 88 millions of francs (or £1,500,000 nearly) in the case of the works undertaken in the Boulevard Magenta. It is precisely the danger of this abuse of the credit of the town that is to be feared, and it is in this respect that the absence of anything like a controlling power in the municipal council of Paris is to be deplored. As the members of this body are all of them merely government nominees, and hold their places only as long as they vote the budget that is presented to them, the conseil municipal of Paris becomes nothing more nor less than a body chosen to give a semblance of legality to the proceedings of the prefect; it is utterly powerless to resist or to oppose any measure that he may have determined. Hitherto there has been no such result as was to be expected from this ignoble parody on municipal government, and Paris has gained in healthiness, in beauty, in convenience; in fact in everything that tends to make life valuable in large towns. The administration of the city funds is confided to a series of officers, who conduct their business with singular skill and attention to the public interests, though it must be confessed that they have allowed the spirit of red-tapeism, in the conduct of it, to gain the ascendancy; but these officers are not empowered to resist the will of the prefect if he should venture to step beyond the limits of his duty. They are only to discharge their functions; they have no deliberative voice, and they must carry into effect the orders that they receive from higher powers than their own. There is no kind of check upon the fancies or the caprices of the Prefect of Paris in fact, and it cannot therefore be a matter of surprise that he should have been misled in many cases, and should have made the mistake of confounding straight streets with good lines of communication, and broad boulevards with efficient means of ventilation. I fear that much of what has been lately executed in Paris, especially in the neighbourhood of the Madeleine and the Parc Monceaux, is liable to this reproach, and certainly it would have been long before the town would have been thus modified, if the conseil municipal had been freely chosen, or if it had correctly represented the wishes of the inhabitants. There is, moreover, this danger about the course that our neigh-

bours have entered upon, that they have created a fictitious demand for labour of the highest and most dangerous class, which they must go on employing; and thus the necessity of always continuing the works at the expense of the town is a constant source of preoccupation to them. The true remedy to this state of things, to the danger of the gradual increase of the debt of the city, and the creation of the fictitious demand for labour, would be, in my opinion, to restore to the municipal council some sort of control over the money of which they are supposed to regulate the application. It is to the facility with which the prefect can create a new debt, and the utter absence of control over his proceedings in this matter, that the danger of the present state of affairs in the city of Paris must be attributed.

In the meantime, the results of the system, in everything that relates to the maintenance of the public works and the comfort of the citizens, must be considered to be as nearly perfect as it is possible to make it. The streets are admirably kept, their surface is admirably paved, and their gutters are washed and swept twice a day, so that every hind of obstruction to the flow of water in the channels is removed with the least possible delay. The footpaths are not so well organised as the roadways, on account of the law which regulates them; but this branch of the municipal service is under a gradual system of change, and the consequences of this are very apparent in the state of the footpaths of the new streets and boulevards. The gas lighting is very well performed, under the direction of the town authorities, and it is carried on with such an amount of luxury in the district around the Louvre and Tuileries, that in the Rue de Rivoli there is a gas lamp at the distance of every fourteen feet, and in the courtyard of the new Louvre there is one every twenty feet apart; nor can this be considered exceptional, as there is the same profusion of light at the Bourse, at all the theatres, on the Boulevards, the Place de l'Hotel de Ville, &c. The service des eaux et des égouts is very efficiently organised, and though Paris is still subject to the nuisance of the night-carts, it is so in a less degree than formerly, and, at any rate, the inhabitants of that city cannot reproach themselves with the pollution of the river by their excreta. The water supply to the town is conducted, at present, on a very confined scale, but much of the inconvenience thus created must be attributed to the conditions under which household property is held in France generally. The city of Paris is, however, energetically at work to cause the insufficiency of its present supply to cease, which desirable object it is calculated will take effect in the course of the next summer. It would not enter into my province to notice the superior decency and cleanliness that are to be observed in the streets of Paris, which form so marked a contrast with the sights and scenes that one is compelled to witness in London; but this must strike every beholder, and give him a higher idea of the municipal organisation of the former city. There are ample provisions made for the markets, the cattle and the wine trade (and the former of these is now to be shortly brought to the immediate neighbourhood of the town); the factories are under strict superintendence, and they are kept from becoming nuisances to the neighbourhood in which they may be placed—in fact, the municipal affairs of Paris are managed with a degree of skill that must excite our admiration, in spite of the facilities that are afforded by the system on which it is based for the indulgence of the aethetical fancies of the prefect, or of a much more august personage. It is to be feared, as has been said, that these will lead the city to great expense, if some check be not soon placed on them. Long lines of streets and long avenues, or boulevards, cannot be constructed without costing a great sum of money; and though it may be desirable to terminate every vista with a building surmounted by a dome, in the style that seems to be the fashion in Paris at present; yet the question of the cost of these improvements must rise up

before the inquirer, and the consideration is forced upon him, whether the circumstances of the town were, or are, such as to render necessary so great an outlay as these domes, and the houses around them, must cost? That which we should do well to imitate in the French system is, the order that prevails in the organization of their services for ensuring the fulfilment of the municipal duties; that which we ought to avoid is, the manner in which the Prefect of the Seine is allowed to dispose of the money of the taxpayers without any real control on their part of the funds so raised, or of the works that are undertaken avowedly for the public benefit. It may not be in the present day that the evil which will inevitably attach itself to the exercise of the irresponsible power of the prefect will be felt; it must, however, sooner or later, entail such consequences as are fearful to contemplate. As long as the system of irresponsible government is confided to intelligent and conscientious men, there possibly may not ensue from it the results that are to be apprehended; but this is always a matter of chance, and the results that would attend the corrupt, or even the unintelligent, use of the power so given must be evident to any one that reasons upon the matter. At present there may be questions raised as to the necessity, or the usefulness, of some of the public improvements executed by the city of Paris; as to the consequences of the future development of the system, it is to me evident that they must result in the embarrassment of the city and the augmentation of the burdens upon the citizens. The very perfection of the organization of, and the unity of system involved in, the services of the municipality seem to me only to disguise the defects of the system of which they form part, for they will allow the working of it to proceed, till it will at length collapse by the debt in which the prefect, or his successor, will involve the town.

I have not thought it worth while in this notice of the municipal organization of Paris, to describe the machinery that is put in motion for the purpose of making the inquiries into the expediency of declaring the works that the prefect may decide upon as being of the class that would come under the law of expropriation *pour cause d'utilité publique*, because the action of this machinery is very simple, and it is easily made to decide according to the wishes of those in power. The question of compensation for the property taken is in France, as in England, very much a matter of chance; that is to say it depends upon the skill with which the proprietor can make and support the claim that he may think proper to advance; for there is no rule by which the jury can fix the value of the land, or can ascertain the amount of the interest that may be attached to the properties or property under conditions that may escape observation. It is, however, the general impression that the compensation that has been generally given in the cases of the new streets and boulevards has been large, and ample for the purpose; so much so, in fact, that the proprietors of land and houses desire now to see the improvements carried on in their quarter, in the hopes of being expropriated in their turn. But this is in itself an evil, as the proprietors can only secure the high prices that they expect, on the condition of the public paying more for their property than it is worth; and the fact of some people getting more for their land does not compensate for the injustice that others may be exposed to. The system in France is, nevertheless so closely like our own in its essential features that I have not thought it necessary to direct your attention to it particularly. I have thought that the municipal organization of Paris, with all its strength, and with all its weakness, was a fit subject for your consideration; and as such I beg to recommend it to your careful study.

DISCUSSION.

Mr. NEWTON WILSON took exception to the introduction into the paper of so many French terms, which he thought would have been more intelligibly expressed to

the meeting at large in English. He had carefully observed the Paris system; and the immediate question which arose for discussion was the comparison of the results between the principles of management in London and in Paris, and the powers of the municipal bodies in those cities respectively. One thing he would especially refer to was the subject of gas. The inhabitants of London had been complaining—not without cause—of the monopoly in and the high price of gas, but they might look upon London as an elysium in that respect when compared with Paris. Gas in the latter city was as complete a monopoly as could possibly be conceived. The gas consumer in Paris was called upon, in the first instance, to deposit a certain sum with the gas company; he had then to pay the expense of putting in the service; and, in the next place, he had to deposit a further sum for the meter, amounting to about 6s. on every burner used. The result was that the gas company was able to divide about 80 per cent. on the paid-up capital out of the monies deposited by the customers as security against bad faith on their part. He quite agreed with Mr. Burnell as to the badness of the pavement in all but the very best streets of Paris. The huge square stones in the back streets were about the worst pavement that could be put down. In the boulevards and principal streets the paving was, however, all that could be desired; and the barbarous custom of treading down the macadamised roads with horses and vehicles, as was done in this country, had happily been abolished in Paris.

SIR THOMAS PHILLIPS, Q.C., thought that just at the present time it required a large amount of courage to stand up in favour of the state of the streets of London, as they were certainly now in a particularly dirty condition. Notwithstanding the hypercriticism of the last speaker, he thought the paper was one of considerable interest; and the justification for the use of the French terms was found in the fact that these phrases applied to official persons, who were distinguished by the names there given to them, and all ambiguity was avoided by using the precise French description of their official position. The condition of the Paris of the present day, as compared with the Paris of twenty years ago, was a subject of considerable interest. Much of the change that had taken place was no doubt owing to the remarkable man now at the head of the French empire, who was now publishing to the world his history of the life of Julius Cæsar, but it would seem that he himself sought rather to resemble another Roman Emperor—Augustus Cæsar, whose boast it was that he found Rome brick and left it marble. It would be something of a similar result which the future historian of the French empire would have to record when he came to sum up the claims of the present Emperor upon the gratitude of the French people. There had been undoubtedly great improvements made in Paris. That celebrated writer, Madame de Staël, in her work on France, took occasion to describe the almost impossibility in her day of getting any public improvements in that country. The municipality met to consider the want of a new street or bridge; after much discussion they came to the conclusion that something must be done: but there must first be a report to a central body, the *Ponts-et-Chaussées*; and perhaps years might elapse in the various passages from board to board, and from office to office, before the work was either carried out or decided not to be done. In contrast to this, it had always been a distinguishing feature of our own country, that when any great public work was projected—whether it was a railway, a bridge, a dock, a canal, or a road—we did not go to a government board to get the work executed, but having once determined upon it, we carried it out ourselves. Undoubtedly there were in this great metropolis many examples of works done by the municipal bodies, but he thought in the majority of cases those works would have been better performed by associations of the people themselves. Moreover, it could not be matter of necessity that the streets of London

should be in the condition they were in now; surely there must be a means of having something like central action. Take, for instance, the breaking up of the streets for laying down gas or water pipes; surely it was not necessary that in the best portions of the year main thoroughfares should be constantly broken up to lay down gas-pipes in the first instance, and re-disturbed at another time to lay down water-pipes. At the period when there was no Metropolitan Board of Works, and when there was no unity of action in these matters, he could understand the existence of these evils; but now he thought they might expect that these works should be undertaken with something like conjoint action and with a minimum amount of inconvenience to the public. In looking at the vast improvements that had been carried out in Paris, there was one subject which had been greatly neglected, and that was the effect of these improvements upon the great masses of the working people. In making a new street, large numbers of the working classes were displaced, without any means being taken to provide them with dwellings elsewhere. He knew that the inconveniences in this respect were very great in London at the present time. He had had occasion to sit for some of the local judges, and many cases occurred of applications for warrants for the ejection of tenants from their habitations, which he was bound to grant; but no one could witness the extent of suffering occasioned by the inability of the poor man to provide himself with another lodging, without feeling that a great evil had been created by turning these people out of their dwellings—bad as these often were, and wanting in all proper sanitary arrangements—without any provision being made for their accommodation elsewhere. The House of Lords, acting—if not on a standing order, at least with a sense of its duty in that respect—required that whenever a railway or other public company took powers to pull down working men's dwellings, they should, in some shape, be bound to provide other accommodation for the persons thus displaced. While on this subject he would refer to the plan now before Parliament for concentrating the courts of law in London. It was, undoubtedly, an important project, and would be highly convenient to all who were connected with the administration of justice; but he hoped, in the prosecution of that plan, it would not be forgotten that a large number of the dwellings of the labouring classes would be pulled down, for whom it was the duty of the authorities to make some provision elsewhere. He believed that civilisation, as they called it, as it progressed in all its various stages, must tread hardly upon the poorer classes in some respects; but it behoved us all to take care that the pressure was lightened as much as practicable, and that in carrying out improvements for the advantage of civilisation and progress, we did it with the least amount of sacrifice on the part of those who were not in a position to help themselves, and who had large claims upon our protection. With regard to the great works executed in Paris, Mr. Burnell had spoken of their great architectural beauty, but there were no doubt differences of opinion on this point. Many people like himself might regret that the picturesque features of the city, and the old historic associations connected with it, had been swept away. He did not mean to say that none of its ancient monuments had been preserved, but the great characteristics of the city seemed to have been wholly destroyed by the improvements that had been executed there.

MR. LAVANOHY could not but express his admiration of the observations which had just been addressed to them by Sir Thomas Phillips, but on going through the paper he felt there was one statement in particular in it which he could not allow to pass unnoticed. The impression conveyed in the paper was that the prefect was the leading if not the sole authority in all those matters of public improvement involving so large an expenditure of money. He was quite sure that an error of that kind had not been intentionally made, but the fact was, that any great public work of the nature described must be accepted and ap-

proved by at least three separate bodies or commissioners prior to its being laid before the Conseil d'État, and if approved by that body it was finally submitted to the Emperor, and, if sanctioned by his Majesty, was referred back to the prefect to be carried into execution. With regard to the cost of many of these great improvements it was well known that this was not borne exclusively by the municipality. The sites having been purchased by the prefect, they were re-sold by tender to companies or individuals, by whom they were disposed of to the different parties who built upon them. He thought it was much to be regretted that some such plan as this was not adopted by the Board of Works in regard to the public improvements in London. As to the large prices paid for land in Paris, he thought that was a matter which we were scarcely in a position to criticise, looking at the enormous sums demanded for building-sites in the City of London at the present time. We must first remove the beam from our own eye before we ventured to take notice of the mote in the eye of our neighbours. There was no question whatever that Paris had been very greatly improved, and history in calmer moments would do justice to the Emperor, and would acknowledge the debt which the French people owed to him.

Mr. BELLOE congratulated Mr. Burnell on having introduced this paper on a subject which was deeply interesting to those who, like himself, were connected with municipal administration in the provinces. The anticipation of hearing this paper had brought him up from Liverpool, because, as a member of the municipality there, he felt that it would be most useful to them to learn what was done in other places, particularly in Paris. On the subject of the grand improvements that had been carried out in that city the paper afforded valuable information, but it did not state how the rates were levied upon the inhabitants for the purpose of these great improvements. He regretted to hear that the water supply of Paris was at present only on a limited scale, but that regret was modified by the statement that an augmented supply might shortly be expected. The water supply of Liverpool and Manchester was happily of the most ample and satisfactory kind, and had been carried out by the municipalities of those towns irrespective of the cost to the public. He regretted that the endeavours made by the Government some eight years ago to effect an arrangement with the water companies of London, by which, under the Board of Works, a general supply of water to London could have been obtained, had been defeated. He desired to express how gratifying it was to him to see the reading of papers of this kind encouraged by this Society, as it was most interesting to know what was being done in other parts of Europe, and he was sure great benefits must ensue from the introduction and discussion of so important a subject.

Mr. WILKINS ventured to think, judging from what they had heard in the paper, that, instead of these improvements resulting from municipal organisation, they had sprung, in fact, from an imperial organisation. He was struck with admiration at the picture of cleanliness and good order which had been presented in the early part of the paper, as regarded the streets of Paris, and began to blush for our own dirty thoroughfares; but when the cost was mentioned he became more reconciled to the present condition of things at home. It might be said that London had outgrown its municipal institutions. Hence there had of late years been created another and more extended authority, the Metropolitan Board of Works, which, however, had accomplished less than was expected of it. Could they not learn a useful lesson from what had been done by the municipal authorities of Liverpool and Manchester? In the case of the latter city a river divided the municipality of Manchester from that of Salford, but there was combined action, and the results were most favourable.

Mr. NASH apprehended that this paper had been brought before them with the view of their being able to derive some useful practical lessons from what was done in Paris.

He thought the municipal institutions of London generally were very defective, and he inclined to the idea that the municipal administration should be made something analogous to the political constitution of the country—King, Lords, and Commons; that while the representative body should be elected by the people, there should also be an intermediate body, not elected, but which on all great matters should exercise its approval or veto. In Paris when a great work, such as a new street, had to be carried out, it was done in a far superior manner to London, for it could hardly be said that any one street had been properly laid out here, and until we could get good lines of thoroughfare London would never be beautiful and convenient.

Mr. FREDERICK HILL remarked that they had several instances before them showing that a despotic government, such as that of France, was not necessary to efficient action. There was the case of Manchester, where in the matters of the supply of water and gas, as well as in other respects, the municipal administration was most admirable. The same might be said of Liverpool and Glasgow, as also of some continental towns, particularly of Hamburg, where municipal government prevailed to the fullest extent, and was entirely dependent on the will of the people. When the disastrous fire occurred in that city, by which a large portion of it was destroyed, the services of an English engineer were not only enlisted in stopping that fire, but the same gentleman was afterwards consulted by the authorities as to the best plan on which to rebuild the portion destroyed. The advice given was to adopt wide streets, building good houses, and taking a broad margin of land besides that absolutely required for the streets. The result was the handsome appearance which that city now presented, and the extra land taken rose so much in value that when re-sold it very nearly paid the expenses of the improvements made. The folly of the authorities of London in not acting upon similar advice given by Sir Christopher Wren, 200 years ago, was now universally admitted. He had had the advantage of seeing Paris at distant intervals, and had witnessed the wonderful improvements that had taken place in that city; the contrast he drew between London and Paris was very much to the disadvantage of his native city. In cleanliness, in the perfect order that prevailed in the streets, and in the absence from them of many of the disgusting exhibitions which were met with in London, Paris must be acknowledged to be greatly in advance of our own metropolis. At the time we were suffering from the offensive state of the Thames, he (Mr. Hill) called upon the Registrar-General, and stated his opinion that, however bad the state of the Thames might be, it was but a small matter in comparison with that of the vast area of the streets of London, by the dirty condition of which the public health was prejudiced. The Registrar-General admitted the facts, but avowed his utter inability to find a remedy, from the difficulty of getting districts and parishes to move in the matter, so that, under the existing municipal system it was almost hopeless to look for any permanent improvement in this respect. If they could induce one district to move he had no doubt the example would spread; but the thing was to make them start on the road to improvement. Mr. Hill also referred to the system of cleansing the streets in Rouen and Havre as worthy of imitation. On the subject of the election of members of the vestries and local boards of health, he thought an alteration of the present system was required; and he mentioned one parish in particular, in which he said the local authorities were elected almost entirely by the publicans of the parish, who appeared to have a repugnance to choosing really respectable people to represent them.

Mr. HANCOCK, in reference to the inquiry how the funds were raised for the improvements in Paris, stated that until recently they were derived entirely from the octroi duties. Not only were articles sent into France taxed at the frontier, but also provisions of all kinds at their en-

trance into the city. Hence the price of food within the city was considerably higher than beyond the barriers, where the octroi duties were not levied, and this had raised the value of land surrounding the city outside the barriers. He thought the people of this country would be very unwilling to submit to such imposts to carry out public improvements.

Mr. JENNINGS remarked that in dealing with the question of comparison, as between London and Paris, in the matter of public improvements, there were some material points which had not been considered. It had been observed that arbitrary power in these matters was the best power when well used, and that more could be effected by this means than by any other; but he trusted we should never wish to introduce arbitrary power into this country. With respect to the margin of land that should be taken in carrying out improvements, that which would apply to Hamburgh would not be applicable to London. The population of this metropolis was so large and so densely congregated that there were seldom any considerable spaces of yard or garden behind the houses. Where they could purchase poor property with large spaces contiguous, it might be profitable to take a margin for purposes of improvement; but practically in London it was far from profitable to purchase poor property. He thought in other respects more might be done in London than had been at present, if the Board of Works, which was comparatively a modern introduction, determined on some settled principle by which they could carry out a series of thoroughfares throughout the metropolis. That could not be done in the case of isolated improvements, but if they previously determined upon a comprehensive plan, it could be gradually carried on to completion. He did not agree with the view that no good streets had been planned in London. He thought the construction of Regent-street was satisfactory on the whole. Our difficulty up to the present time existed in the fact that the Board of Works had not the power to insist that streets should be laid out in a particular line. He thought it desirable that such a power should exist somewhere. He agreed that the Board of Works as at present constituted was not very popular, but there were very many able men on it, and he hoped they would be chosen as a committee to take up this important question. With respect to the dirty state of the streets, there was no necessity for its continuance. The streets in the City were swept every night, and he saw no reason why the same system should not be adopted throughout London generally.

Mr. DALTON was sorry to find that the Board of Works, of which he was a member, was still the subject of a considerable amount of censure, but he thought a little consideration of what they had done, and were now doing, would greatly alter the tone of those observations. They had been told this evening that the Board was answerable for the constant disturbance of the streets, in the laying of gas and water pipes; but he begged to state that they had no power to prevent this. Parliament gave gas and water companies despotic powers to take up the pavements where they pleased; and it was only by an Act passed the Session before last, that the Board of Works had power conferred upon them to prevent the entire stopping up of any street, without their sanction; previously to this, two great parallel thoroughfares—such as Holborn and Fleet-street—might have been blocked up at the same time. In the recent new streets formed by the Board, they had introduced subways, but these were opposed by the gas and water companies, and they would not use them when made. The Board could go no further than they had done in that direction. With respect to the great improvements carried out in Paris they had been told that a taxation of £3 15s. per head of the population had been the result; whereas the whole rates in respect of the main drainage and improvements of London did not amount to more than 9d. in the pound on the local assessment, or about 10s. per head of the population. The Board was asked to make larger public improvements. Where was the money to

come from? Would the inhabitants like to submit to octroi duties as they did in Paris? There was an outcry the moment an increase of the rates was spoken of. With respect to the Vestry, which was said to have been elected solely by the publicans of the parish, that arose entirely from the other parishioners not taking the trouble to look after their own affairs. It had been urged that the Board of Works ought to decide upon a comprehensive and definite plan of public improvements, but he might state that the Board had plans already before them involving an outlay of no less than £26,000,000. The present generation were called upon to bear the burden of the neglect of their forefathers. London had grown to a great extent without the thoroughfares being commensurately increased. The public were very hard upon the Board of Works; they would not give them the straw wherewith to make the bricks. The great work of the main drainage of London, for which the Board was originally constituted, was nearly completed. They had grappled with the question on which all previous Commissions had failed; and within the next two months the whole of the sewage of the south side, and two-thirds of that of the north side of London, would be conveyed away a distance of twelve miles below London Bridge. Much progress had also been made in the Thames embankment, which he did not hesitate to say was the finest work that was ever undertaken for London. The measures of the Board of Works would relieve the Thames of its pollutions; but their worth would to a great extent be nugatory if towns situated on the Thames above London were permitted to cast their sewage into its waters to be brought down by the stream. He hoped some legislative measures would speedily be taken on that subject.

The CHAIRMAN, in closing the discussion, said not the least interesting remarks were those of the last speaker, who had defended most ably, and, as he (the Chairman) believed, most accurately, the proceedings of the Board of Works, undertaken as they were under very great and special difficulties. A new system had been thus introduced into this metropolis which was calculated to produce effects almost, if not quite, as great as those in Paris, where the machinery by which they were brought about was such as would not be tolerated in this country. There was one observation in the paper which he did not think the facts brought before them justified. It was to the effect that Paris had gained in everything that tends "to make life valuable" in large towns. What had Paris gained? Some very remarkable streets and a great deal of elegant architecture. But let them see also what it had lost. Notwithstanding all the improvements in Paris, the sanitary condition of that city was inferior to that of London. How was that to be accounted for if London deserved the amount of abuse heaped on it? The real fact was that the health of the poorer classes was cared for in a higher degree in London than in Paris. Whatever might be the beauty of Paris, it was obtained by a heavy burden of taxation—enormously greater than in London—so great as to excite our surprise that it could be borne by the people. Although, however, the cost was enormous, the indirect return obtained by making Paris the centre of attraction for all the world ought not to be lost sight of. Then the question came, could we so beautify London as to make it a greater centre of attraction than Paris, and whether an equal expenditure in London would produce results equal to those at Paris? They must look to the matter of climate in the first place. London was subject to changes of climate and weather which were unknown in Paris. In the latter city the winter was cold, but dry and clear; in summer the heat was greater, but there were fewer wet days. In the matter of the cleanliness of the streets, the continuance of fine dry weather, both in summer and winter, was a great element. Then, again, there were questions involved as to the difference in the habits of the people. Would our population consent to be concentrated in flats, as was the case in Paris, with scarcely

a house occupied by an independent family? Could the habits of the people be so altered as to forego that domestic isolation which was so characteristic of the English? While we continued to have separate dwellings, London must necessarily be spread over a very large district, and its roads and drains must be of such great extent, compared with Paris, that the difficulties were increased in proportion. The gentleman from the north (Mr. Beloe) stated that he attended this evening in the hope of gaining some information on points of local government, and he had alluded with great modesty to the remarkable works at Liverpool and Manchester for the water supply of those great towns. They were the first two cities in England which had applied the principle of providing a water supply without regard to the cost to the individuals using the water. They had bought a large tract of country, the rainfall of which was collected in reservoirs, conveyed to Liverpool and Manchester, and distributed without stint to the population, the whole cost of the service being maintained by the municipal authorities. But could such a thing be done in London? The geological and geographical formation was different. Liverpool was by the seaside almost on a dead level, and its water came from a high district 30 or 40 miles to the eastward of it, and was brought down by the slopes to the town. They had no such geographical facilities in London, and it would be far more difficult to distribute water by the means employed at Liverpool than by the present system. When they talked of hindrances and delays in public improvements occasioned by Vestries and Local Boards, they must look at the fact brought before them, that in Paris every public work had to pass under the cognizance of no fewer than eight distinct boards or commissions; and, under these circumstances, it was to be inferred that there was as much obstruction in getting through improvements in Paris as there was in this country, with all its faults. For his own part, he would rather see some of our difficulties, and some of our dirt, too, than have the alleged facilities and cleanliness accompanied by the despotic power which prevailed on the other side of the channel. He was sure they would join him in a cordial vote of thanks to Mr. Burnell for his valuable paper.

The vote of thanks having been passed,

Mr. BURNELL, in acknowledging the compliment, said that it was too late in the evening to attempt to answer the various observations that had been made upon his paper; besides that, in consequence of his infirmity of deafness, he had unfortunately lost much of what had been said. He would, however, take the liberty of observing, with reference to the observations made by Sir T. Phillips and Mr. Dalton, upon the advantage of placing the gas and water mains in the same sub-ways, that Mr. Belgrand, who had considerable experience in laying of both gas and water pipes in this manner, had last year given evidence before the Committee of the House of Commons against that style of construction. Mr. Burnell added that he himself witnessed, on the 25th of last month, the effects of a serious accident which took place in Paris, in consequence of the adoption of the subways, and he warned the public that there were many dangers attending them. In this case, the gas and water-mains were laid in a sub-way, that was formed in the spandrils of the arches of the Pont d'Austerlitz. For some reason, the gas company required to alter their main; they, therefore, proceeded to shut off the gas on both sides of the bridge, and they left the gas time to escape, as they thought; an explosive mixture was, however, formed, and upon a light being accidentally presented, an explosion took place; the results of this were that one man was killed, three were wounded and carried off to the hospital, the water-main was started, and the pavement of the bridge was torn up throughout its whole length; the damage to the company was said to have

been as much as £10,000. With regard to the observations of the Chairman, he (Mr. Burnell) must persist in saying that Paris was a city in which life was agreeable; and as a proof of this, he would only mention the fact that the mortality of that city was now very little above that of London. It appeared from the returns for the three years, ending 1862, that the death rate per 1,000 in Paris was 24.918, whilst that of London for the same period was 23.077. Mr. Burnell, in conclusion, said that he should be happy at any time to answer any letters that might be sent to him on the subject that he had laid before the meeting in the course of the evening.

Proceedings of Institutions.

LEEDS MECHANIC'S INSTITUTE.—The annual meeting was held on Friday, January 27th, the mayor (President) in the chair. Mr. W. J. Neild, hon. sec., read the report, from which it appeared that there had been an increase of 26 members during the past year in the subscribers of the 12s. class, and in the 5s. ladies' class. In the proprietary members and 16s. subscribers there had been a decrease. The general summary of the library issue showed a decrease in the number as compared with the previous years' circulation, the half this decrease being in fiction alone. There had been a great increase in language, the result of an addition to the library of French and German literature. The Committee regretted that, owing to the Telegraph Company having advanced the charge for telegrams 50 per cent., they had been compelled to discontinue them. They had, however, introduced a considerable addition to the newspapers. Twenty-four lectures had been delivered. The balance-sheet showed a deficiency, on the whole of the departments, of £21 18s. 5d. Upon the year's income and expenditure there was, however, really a profit of £45 9s. 1d., which had been reduced to the above loss by the school fees, &c., accounted bad. The reports as to the state of the Boys' School, the Ladies' Educational Institute, and the various classes, were most satisfactory. The School of Art also continued to improve in numbers and efficiency; the number of pupils had increased to 7,430; by the return of statistics received by the Science and Art Department, the school had a larger number of pupils connected with it than any school in the United Kingdom; and it had the widest local influence of any school of art. The financial statement as to the different departments was as follows:—The institution proper, income £776 4s. 7d., loss £45 2s. 2½d.; ladies' school, income £789 19s. 8d., profit £55 16s. 7d.; boys' school, income £699 7s. 2d., profit £51 8s. 0½d.; School of Art, income £468 11s. 4d., loss £86 17s. 11d.; evening classes, income £85 5s. 6d., profit £2 16s. 7d.; the new building £2,540 1s. 2d., balance in hand £2,481 1s. 8d. A special vote of thanks was passed to the president, Mr. J. D. Luccock, Mayor of Leeds, for the valuable services he had rendered during the year, and a richly-mounted cane was presented to him.—A paper was recently read by Mr. James Hole, the successful competitor for the prize of £5, offered by the Mayor of Leeds, for the best essay on "The Dwellings of the Working Classes in Leeds," the adjudicators being Messrs. W. B. Denison, T. Dawson, and John Taylor. Mr. Hole announced that his essay would shortly be published, and would be illustrated by a series of engravings of Akroydon, presented by Colonel Akroyd, and of the Crossley Cottages, presented by Mr. John Crossley. Mr. Walter Smith, head master of the Leeds School of Art, had also promised to contribute some drawings of the buildings erected in Leeds by the Model Cottage Building Society.

In conclusion, the author stated that he greatly doubted whether there was any instance of a drought of a similar intensity and duration ever having occurred in that locality. During the whole seven months of its continuance, besides fulfilling their statutory obligations to the millowners on the Eak, the Water Company were able to maintain a supply to the inhabitants of Edinburgh, Leith, and Portobello, which only during six days, and these in the month of October, fell so low as 451 cubic feet per minute, or 20-23 gallons per head per day to a population of 20,000 persons.

Fine Arts.

EXHIBITIONS.—The collective exhibition of the works of the late painter, Hippolyte Flandrin, is now open in the new building of the School of Fine Arts in Paris. The proceeds are to go to the fund for assisting unfortunate artists.—A fine art exhibition is announced to open at Alençon on the 20th of May next.—The twenty-ninth annual exhibition of the Rhenish Association commences on the 15th of April. This society carries round its collection to all the towns belonging to the Association, namely, Fribourg, Strasbourg, Mayence, Darmstadt, Mannheim, Karlsruhe, and Stuttgart, allowing from twenty-five to twenty-eight days to each place, and completing its labours on the 19th of October.—Besançon opens its exhibition on the 15th of March; Bordeaux, on the 1st of next month; Mort, on the 1st of May; Saint Briac, in the same month; and Toulouse, on the 15th of June.—The exhibitions of Lyons and Pau are now open. The Central Union of the Beaux-Arts applied to Manufactures, whose recent establishment of a museum and library in the Place Royale was described in the *Journal* a few weeks since, announces its annual exhibition to be held in the Palais de l'Industrie in August, and offers 300 francs for the best model or design for the medals to be awarded on the occasion, and which are to be in gold, silver, and bronze.—A general exhibition of industry and industrial art is to open at Chaumont at the same time as the annual agricultural show, which opens on the 20th of May.—Lastly, the Polytechnic Society of Stettin proposes to organise a general industrial exhibition, under the protection of the Prince Royal of Prussia, to open on the 15th of May and close on the 30th of June in the present year. It is proposed to cover a portion of the cost by charging exhibitors a very small tax, regulated either according to the value of their contributions or to the space occupied by them.

THE CARIATIDES OF SALONICA.—These well-known statues have been purchased by the French Government. Mr. Miller, who went out in May last on a mission from the Emperor, to make excavations in the island of Thessa, while waiting at Salonica for a boat to convey him to his destination, made a careful examination of the ruins of the Temple of the Cariatides, which for some years has been built against and enclosed within walls; he found the statues themselves deplorably mutilated, and it was evident, from the marks of recent fractures, that the work of destruction was progressing rapidly, and that before long these vestiges of ancient art would cease to exist altogether. Mr. Miller proposed to purchase them from the supposed proprietor, but this man asked such an exorbitant price as immediately put an end to that idea. Presently, however, it was ascertained that the Cariatides did not belong to the person in question, but to the Turkish Government, which, however, attached no value to the famous ruin, and had allowed it to be enclosed as above described. This fact discovered, Mr. Miller obtained the aid of the French Consul, the Marquis de Poncharra, and of the Pacha of Salonica, and, finally, with the assistance of the French Ambassador at Constantinople, Mr. Miller was authorised to carry the Cariatides to France. Another account of the transaction

has appeared in the *Journal de Constantinople*, in correction of which the preceding statement has been published in a Paris paper.

ROYAL ACADEMY OF BELGIUM.—The Brussels Academy has issued its programme for the current year, and a portion of that for the succeeding session. The subjects selected for memoirs in the former case are:—1st. On the methods of teaching the graphic and plastic arts in the Low Countries and the province of Liège in all ages. 2nd. History of mural painting in Belgium, and polychromatic application to architecture, with the characteristics and methods of each epoch and each school. 3rd. The system of estimates for great architectural monuments erected during the middle ages, what portions fell to the architect or director of the work, and what were more particularly in the province of artists and artisans acting individually or in corporate bodies; also the modifications which have since taken place to the present time. 4th. History of landscape painting, with its progress and transformations, from the time it was employed as a mere accessory to that when it became a distinct study. The prizes are, for the first subject, a gold medal, of the value of 800 francs; for the second, 1,200 francs; and for the last two, 600 francs each. The subjects announced for the following session are:—1st. Analysis and appreciation, in a scientific as well as artistic point of view, of the principal methods of instruction in drawing which have been in use from ancient times to the present day; the value and influence of each. 2nd. Rubens as an architect. There are many buildings in Antwerp and Brussels attributed to Rubens—is this tradition founded on fact, or must the style which predominates in these buildings be merely attributed to the influence of the works of Rubens and his school?

Manufactures.

EXHIBITION.—At a general meeting of millers, to be held in Dresden, Saxony, in August or September next, there will be an exhibition of all mill productions, as well as mill stones, and all other implements connected with mills. Exhibitors from all countries are to be admitted.

MANCHESTER WORKMEN'S EXHIBITION.—On Monday afternoon, the 20th instant, a meeting was held at the Royal Institution, Manchester, for the purpose of opening an exhibition of productions contributed by working men. The lecture-hall was well filled. Sir J. KAY-SMUTTLEWORTH, Bart., presided, and there were present the Mayors of Manchester and Salford, the dean of Manchester, &c. The meeting was addressed by the Chairman, Mr. Alderman Heywood, and the Dean of Manchester. Amongst the objects shown may be mentioned some carvings of fruit and flowers, in Caen stone, by Mr. Green, a Manchester sculptor; a piece of stone carving, by Mr. W. Fasana, called "The Invader"—a serpent who is stealthily approaching a bird's nest; a carving of a dead canary, in box-wood, by a workman employed by Mr. Cowan; also one of Whittington listening to Bow bells. There are carvings in ivory, small models of steam-engines and machinery, architectural models of buildings, &c.

MIDLAND COUNTIES INDUSTRIAL EXHIBITION.—A public meeting was held at Nottingham on Monday, the 20th instant, for the purpose of promoting a working man's industrial exhibition for Nottingham and the midland counties. There was a large attendance of the working classes, and several gentlemen addressed the meeting, strongly urging that such an exhibition should be held. A resolution in favour of this being done was unanimously adopted.

STANDARD OF ELECTRICAL RESISTANCE.—Copies of the standard chosen by the Committee of the British Association on Electrical Standards, appointed by the British Association in 1861, can now be procured by application to Mr. Fleeming Jenkin, 6, Duke-street, Adelphi, Secretary

to the Committee, the cost of a unit coil and box being £2 10s. The standard is a close approximation to 10,000,000 metre-seconds in Weber's absolute electro-magnetic system, determined according to new and careful experiments made by different members of the Committee, and the copies are constructed of an alloy of platinum and silver, in a form chosen as well adapted for exact measurement. The want of a generally recognized standard of electrical resistance has been universally felt, and led to the appointment of the Committee, who now express a hope that the motives which have led to their present choice, and which are fully explained in the several reports published by them, will induce all interested in the progress of electrical science to assist in procuring the general adoption of the new standard.

Commerce.

TOBACCO.—The exports from the United States of America during 77 years, in periods of seven consecutive years, are as follows:—

AVERAGE SHIPMENTS IN SEVEN YEARS.

Period.	Hhds.	
1787—1793	87,836	The first period is the seven years after the revolutionary war. Second and third, during the European war. Fourth, includes war with Europe of 1812, preventing shipments during last two yrs.
1794—1800	71,131	
1801—1807	81,112	
1808—1814	31,141	
1815—1821	73,358	The fifth to ninth periods show a steady and constant increase during 35 years' peace.
1822—1828	85,207	
1829—1835	95,567	
1836—1842	100,423	
1843—1849	126,267	Tenth, a decline, at the end of which, in 1857, prices reached their highest point ever obtained in the three markets, in proportion to quality. The last shows an average increase over every preceding one, notwithstanding that during the last three years the markets of Virginia have been closed.
1850—1856	116,274	
1857—1863	139,562	

ALLOYS OF SILVER.—The increasing rarity of silver lately induced the French Government to form an alloy for monetary purposes, consisting of 835 parts of silver and 165 parts of copper, and pieces of 50 centimes, with the figures 835 stamped upon them, are actually in circulation. The fabrication presents no difficulty, the malleability is nearly the same, and the slight yellowish tinge can only be detected by rigid comparison. M. Eugene Peligot has been making experiments, with the view of substituting zinc for copper in the alloy. The process employed is very simple, and the results of combination in various proportions are said to be very satisfactory. The fusibility of the new alloys is greater than that of the alloys of silver and copper; they are very sonorous, elastic, and malleable, and no verdigris is formed by contact with acids. The most economic method of restoring the coinage would be the employment of the old silver in the new alloy. One per cent. of zinc is already employed in the French copper coinage, and this small proportion suffices to give qualities to the coinage which copper does not possess. The small Swiss coins made at Paris contain zinc associated with copper, nickel, and silver. M. Peligot has formed alloys in the following proportions:—Silver, 950, zinc, 50; silver, 900, zinc, 100; silver, 800, zinc, 200. Ternary alloys—silver, 900, copper, 50, zinc, 50; silver, 800, zinc, 100, copper, 800; silver, 835, copper, 93, zinc, 72.

Colonies.

TASMANIAN PRODUCTS FOR THE NEW ZEALAND EXHIBITION.—Recent accounts state that, though the sub-

scription list is at present totally inadequate to the occasion, the products which have been sent in to the committee, or are ready when called for, are such as to be creditable to the colony, more especially considering the shortness of time allowed for appealing to the public. The list contains a great variety of Tasmanian timber in the shape of ordinary market woods, of blue gum and stringy bark, railway sleepers, &c., Florentine marble granite from the east coast, wheat, oats, barley, oatmeal, flour, ale, &c., Tasmania-grown field and garden seeds, silkworms, a wool press, a tobacco cutting-machine, &c.

TASMANIAN AGRICULTURAL SHOW.—The annual exhibition of the Northern Agricultural Society, which is now regarded as one of the principal events of the year, came off at Longford on the 2nd November last, and was beyond every other show most successful. The exhibition of horses, cattle, and sheep was unparalleled. What with the large number and general excellence of the entries, the judges had no easy task to perform. The attendance was about the same as usual, upwards of 2,000 people being present, and comprised visitors and buyers from all parts of the island, even the extremities—Hobart Town and Falmouth. The amount of admission fees taken at the gate was £108.

NEW SOUTH WALES.—AGRICULTURE.—The returns show that the wheat harvest was by no means so complete a failure from the rust as was generally anticipated. There was half a harvest—fully half of the average of the previous ten years. The produce is put down at 808,919 bushels; in the previous year it was only 1,054,954 bushels, and in 1856, the most productive year of the decade, it did not exceed 1,756,964 bushels. As the wheat harvest was known to be a total failure in some places, it seems to follow that in some others the damage done must have been very slight. The area of land put under wheat was 103,942 acres, less not only than in the preceding year, but than in the four preceding years.—The tobacco manufacture shows a very marked increase, the quantity produced in 1863 being 36,443 cwt. as against 3,755 cwt. in the previous year, and 1,587 cwt. in 1861. The principal seat of the manufacture is at Maitland. Recent attempts to grow tobacco on the Lachlan seem to promise favourably, and there seems every hope that the western district may become the seat of a prosperous tobacco agriculture as well as of a tobacco manufacture.—The quantity of sugar refined was 169,280 cwt., which was a slight increase over that of the previous year. There are five establishments in the colony, but only two of them were at work. This department of manufacturing industry would receive a considerable impulse if agricultural industry would but take the turn of sugar cultivation. Experiments tend to show that the soil and climate are admirably adapted to the growth of the cane, and that the profit on the operation would be far greater than can be obtained from any other branch of agriculture.

Obituary.

Mr. SAMUEL GREGSON, M.P. for Lancaster, died on Wednesday the 8th of February. He was in his place in the House of Commons on the Tuesday evening. Shortly before three o'clock on the following morning he was seized with illness at his house, Upper Harley street, and died in three-quarters of an hour afterwards, in the 70th year of his age. He was the eldest son of the late Samuel Gregson, Esq., who filled the office of Mayor of Lancaster in the year 1825. Brought up in early life to rely on the result of honest perseverance and steady application, the character of Mr. Gregson was soon appreciated in the counting-house at Liverpool, where he commenced his commercial career. He was selected by his employers to positions of trust and confidence unusual for so young a man, and in course of time proceeded to Calcutta, where

he developed a business, and ultimately returned home, establishing a firm in London which carried on commercial operations of great magnitude in the China trade, and for many years has continued to hold a high and respected position. In 1837, Mr. Gregson unsuccessfully contested the borough of Lymington, in Hampshire, and in 1847 he was first returned in the liberal interest for his native town, Lancaster, but was unseated on petition. At the next general election he was again returned to Parliament, and has continued to represent Lancaster ever since. For sixteen years he advocated a reduction in the duty on tea; he felt that to tax heavily the produce of China, while the Chinese were compelled to admit our manufactures at a low tariff, was unjust, apart from an anxious desire to see his own countrymen supplied at the lowest cost with such an important article. Year after year, therefore, as chairman of the East India and China Association, Mr. Gregson urged the subject on successive Chancellors of the Exchequer, and in February, 1863, he presided over an influential meeting of merchants and others for the purpose of obtaining a reduction, and in a few weeks afterwards had the satisfaction of hearing, in unusually complimentary terms, from Mr. Gladstone that the tea duty was reduced to one shilling per pound. In a similar spirit, though with less success, Mr. Gregson has urged the importance of reducing the duty on salt in India. Everything connected with the East met with Mr. Gregson's earnest attention, and as one who had realised the tediousness of corresponding with India round the Cape of Good Hope, he justly appreciated the facilities of the overland route opened up by Lieutenant Waghorn; he was an early promoter of the Red Sea telegraph, and had recently been occupied in the important question of establishing railways in China. He was respected by all parties. Though making no pretensions as an orator, whenever he rose in Parliament he was always listened to with respectful attention; and his advice, particularly on matters connected with the trade of India, was highly valued. He was always known as a hard working member of the House of Commons, regular in his attendance, and zealous in the performance of his duties. The building of a beautiful church upon the Moor, at Lancaster, was due to his liberality, as well as some handsome baths and washhouses. He was elected a member of the Society of Arts in 1853, and served for some time on the Council, where his advice was highly valued by his colleagues, by whom his loss is much regretted.

Notes.

MEMBERSHIP.—PROTECTION TO INVENTIONS.—On Tuesday Mr. Milner Gibson, in committee of the whole house, obtained leave to bring in a bill for the protection of inventions and designs exhibited at certain industrial exhibitions in the United Kingdom. The Dublin International Exhibition (1865) Bill was read a third time and passed.

ROYAL SCHOOL OF NAVAL ARCHITECTURE AND MARINE ENGINEERING.—A course of three lectures, on "Magnetical Errors, Compensations, and Corrections, with special reference to Iron Ships and their Compasses," is to be delivered in the Old Lecture Theatre of the South Kensington Museum, on Thursdays, March 9, 16, and 23, 1865, from four to five o'clock p.m., by George Biddell Airy, Esq., Astronomer Royal. The subject will be treated under the following heads:—1. Terrestrial magnetism, and the magnetism of permanent magnets. 2. Transient induced magnetism of iron. 3. Sub permanent magnetism of iron. 4. Correction of magnetic disturbing forces. 5. Magnetism of ships, especially of iron ships, and correction of their magnetic disturbing forces on the ship's compass. At the close of each lecture, the Astronomer Royal will wait to give separate explanations to any individual members of the class. Though single lectures

may have previously been given, it is believed that this will be the first course of lectures on this important subject which has been delivered in the country.

RAIN.—In the *Journal* of last week, under the title "What is an inch of rain?" appeared an extract from the weekly return of the Registrar-General, respecting the rainfall. M. Petit, the director of the Observatory of Toulouse, speaking of the late heavy rains, says:—"The quantity is not so unusual as at first sight would appear. The average annual fall is about 60 centimètres, rather more than two feet English, spread over about a hundred rainy days, thus giving an average fall of about six millimètres for each day, or about six litres, 10 to 11 pints English, per square metre. The average of the heavy rains of the 15th, 16th, and 17th of January, in the present year, rose to about nine millimètres. Greater falls have often occurred in France. On the 19th of September, 1844, 35 millimètres of rain fell at Toulouse in thirty minutes; and on the 10th of August, 1859, there fell 59 millimètres in two successive storms of about forty minutes each in duration. . . . In recalling the impression of terror created by the sight of a precipice, one is inclined to ask how it is that we are not terrified at such enormous quantities of water being suspended over our heads. But the question appears under a still more extraordinary aspect when we consider the amount of heat required to vaporise all the water which we receive in the form of rain. When we remember that in the tropics there falls about two metres of water per annum; that in our climate we have never less than 50 or 60 centimètres; and that the masses of snow in the polar regions must also furnish a great quantity of water, it will readily be admitted that the annual rainfall must be, at least, equal to a stratum of water all over the globe of 50 centimètres, upwards of 19½ inches English. . . . It is easy, with these facts given, to see that the evaporation caused by the heat of the sun must render to the atmosphere about 175,000,000,000 cubic metres of water per day, or rather more than 2,000,000,000 of litres a second. . . . And yet the furnace is 38 millions of leagues distant from us!"

TEA-MAKING.—A correspondent of the *Times* says he finds, from careful inquiry, that it is usual to brew 64 pints from 1 lb. of tea leaves, to which are added 4 lbs. of sugar and 8 pints of milk—72 pints in all.

MEETINGS FOR THE ENSUING WEEK.

- MON.** ... Society of Arts, 8. Cantor Lectures. Professor Ansted, F.R.S., "On the Applications of Geology to the Arts and Manufactures." (Lecture IV.)
B. Geographical, 8½. 1. Mr. C. R. Markham, "On the Origin and Migrations of the Greenland Esquimaux." 2. Capt. Sherard Osborn, "Remarks on Dr. Peterman's letter on North Polar Exploration."
ACTUARIES, 7.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MARCH 8.—"On Cotton Gins." By ZERAH COLBURN, Esq.

MARCH 15.—"On Marine Engines from 1851 to the present time." By W. PROCTER BURGESS, Esq., C.E.

CANTOR LECTURES.

The Second Course of Cantor Lectures, the subject being "The Applications of Geology to the Arts and Manufactures," by Professor D. T. ANSTED, M.A., F.R.S., is now being delivered on Monday evenings, at Eight o'clock, as follows:—

MARCH 6TH.—LECTURE 5.—On Stratified Deposits of Minerals, as Coal and Iron Ore, usually obtained by Mining Operations, and on Mining Methods for such Deposits.

MARCH 13TH.—LECTURE 6.—On Metalliferous Veins or Lodes and their Contents, and on the Extraction of Metalliferous Minerals from Lodes.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

ART-WORKMANSHIP PRIZES.

In reply to the letter addressed by the Council to the principal City Companies, the following has been received from the Salters' Company:—

Salters' Hall, 14th Feb., 1865.

SIR,—The application made to the Master and Wardens of the Salters' Company, for aid in forwarding the endeavour of "The Society for the Encouragement of Arts, Manufactures, and Commerce," to improve the artistic taste and skilful manipulation of the art-workman, by giving prizes for the best works executed from examples provided by the Society, was laid before the Court of Assistants at their recent meeting. The application was favourably entertained, and I have the pleasure to inform you that the Salters' Company resolved to become annual subscribers of ten guineas in aid of the fund for granting prizes for improving the artistic taste and skilful manufacture of the art-workman, and I enclose a cheque for the first year's subscription. I am, &c.,

EDW. THOMPSON,
Clerk of the Salters' Company.

To P. Le Neve Foster, Esq.

Proceedings of the Society.

CANTOR LECTURES.

SECOND COURSE.—FOURTH LECTURE.—MONDAY, FEB. 27.

STONES USED IN CONSTRUCTION, &c.

Professor ANSTED commenced by stating that from the consideration of materials obtained from superficial accumulations, not regularly stratified, we pass to stratified and igneous rocks, removed either by quarrying or by mining, and he proposed to bring under notice the facts determined concerning stones used for constructive purposes. So far as their uses extend, these minerals may be grouped in many ways. They are required for constructive purposes—(1) as squared or rough stones, fit for building walls of houses, churches, and palaces; (2) for paving and roofing; (3) for road-making; (4) for the finer kinds of construction; and (5) for artistic purposes. The same kind of stone is often used for two or more of these purposes, but, as a rule, the less perfectly crystalline kinds, being cheaper and more easily worked than the others, are used for commoner purposes; the harder kinds, capable of receiving a high polish, being reserved for more artistic purposes. Commencing with building materials, we may regard them as of three classes—granite, sandstones, and limestones; but there is another division into two classes, namely, those worked by the pick or by wedges, and those worked by the mallet and chisel. The latter are freestones, and include marbles, limestones, and sandstones. The former include granites, quartz rocks, conglomerates, &c. Granites are procured on a large scale from Cornwall and Devonshire, where they are worked with facility and cheapness; others are from Peterhead and Aberdeen. Others, harder than either and of a darker colour, are from Guernsey, Malvern Hills, and Leicestershire. Granite consists of crystals of quartz, felspar and mica in crystalline quartz. The mica is frequently replaced by hornblende, the result being aenite. The felspathic portion of the stone also is sometimes *albite*, in which the alkaline element is chiefly soda instead of potash. Granite may be coarse or fine grained. Some kinds are brittle and others tough; some break along lines of natural fracture, while others resist regular fracture. Chemically, granite is a silicate of alumina and potash, with a little iron and lime, soda sometimes replacing the potash and magnesia the lime. To a certain extent, granites are mixtures of crystalline minerals in various proportions, and an average variety contains from two to three-fifth parts of crystals of quartz or crystalline quartz, about the same of felspar, and the

remainder mica. Granite possesses a mean specific gravity of 2.66, so that the cubic foot weighs 166½ lbs. Fourteen cubic feet to the ton is the usual estimate. Its toughness is great, and varies much in different samples. Fresh unweathered granite will bear any direct crushing weight to which it can be exposed. Granite contains about 0.8 per cent of water, that can only be driven off by continued exposure to heat. In its ordinary state, and containing this quantity of water, it is still capable of absorbing about one-fourth more (or 0.2 per cent.), when placed in water for a few hours. Expressed in another way, a cubic yard of granite contains something more than 3½ gallons of water, and can absorb nearly a gallon more on being placed in pure water for a short period. To a small extent granite is soluble in pure water and hydro-chloric acid. The solubility of granite in pure water and hydro-chloric acid is among the tests of its value. A specimen was found to lose 0.25 per cent. of its weight in water, and 5 per cent. in acid. For various public works, as bridges and harbours, and for some public buildings granite is adapted, but its hardness and the cost of working, limit its use to works of practical utility where durability is essential. But good varieties require to be selected, and some granites are not more proof against weather than limestones. Basalt is a material used for rough walls and road material. In this rock a large percentage of iron is a prevailing feature, while the percentage of potash and soda is not excessive. The tough nature of this rock, and the mode in which it weathers, leaving round lumps, separated by powdery rubbish, are due partly to composition and partly to the mode of formation of the rock. The columnar form of basalt is due to the same causes. Greenstones are varieties of basalt, and *trap* is a name given to rocks of this kind. All are useful for road metal. Of other rock not freestones, quartzites and quartz conglomerates, are rarely used for other than rough walls. Indurated schists are durable, but not ornamental, and very difficult to work into any convenient form. Indurated sandstones are more valuable and are occasionally employed in engineering works. Flag stones are valuable for paving, but not available for other purposes, except that they are sometimes used for party walls. These materials are hard, dense, non-absorbent, and resist atmospheric influences. They are, however, difficult to manipulate, and cannot be recommended except for special uses. Paving and road material must be considered among these. In quarrying granite the nature and position of the system of joints and natural fractures that affect the rock are important considerations, and depend on the geological axis of the district and the direction of elevation of the rocks. In granites only certain veins are valuable. These are of small extent compared with the mass of the stone, and are enclosed on either side by walls of inferior material. Granite is irregular in its composition; but the larger the mass the less are the irregularities perceived. In England the fine and durable qualities occur larger in Cornwall and Scotland than in Guernsey or Charnwood Forest, and the granite for extensive works should be sought for rather in the former than the latter localities. Freestones are stones that may be worked with mallet and chisel, and sculptured without difficulty. Of these some are crystalline, as the varieties of marble, dolomites, alabaster, malachite, spars, serpentine, &c. Of fine marbles only Carrara yields great supplies. Carrara marble is obtained from a quarry nearly midway between Leghorn and Genoa, and close to the bay of Spezzia. The quarries are very accessible. The veins of marble are in the Apennines, and include many varieties. The marble is quarried by first loosening the large masses by blasting, after which wedges are applied until the blocks are detached. The finest blocks are removed in the rough, but the others are shaped into oblong squares. From two to three thousand men are employed constantly in the quarries now in work, which number from thirty to forty for common kinds, and ten or twelve for fine marbles. The annual production

exceeds 50,000 tons. Marbles of inferior quality are quarried like limestones. The best black are found in Derbyshire, where they form part of the carboniferous series. Red are rare and valuable. Yellow are chiefly found in Italy. The mixed colours are more common. There are numerous varieties found in England, chiefly in Derbyshire and Devonshire. Ireland also contains many. India is rich in marbles. On the continent of Europe, Belgium, France, Spain, Portugal, and many parts of Germany all yield excellent varieties, worked cheaply for ordinary purposes. Serpentine is used as a kind of marble. It is a silicate of magnesia, coloured by metallic oxides, of iron, nickel, and chrome. The Lizard rock contains veins of extreme beauty, remarkable for its brilliant colour contrasted by the purest white. The Italian serpentine (*ophite*) is different and far less brilliant. Irish Connemara marble is a variety of serpentine. Alabaster, of pure white or grey colour, and transparent, is a very beautiful material, very easily worked, and inexpensive, but it will not stand exposure. It is obtained in large quantities in England, but the largest and best supply is from Italy and Greece. Ordinary freestones are either limestones or sandstones; the former consisting of two groups—the limestones properly so called and the magnesian limestones, or dolomites. Of sandstones, the Craigleith is one of the best. It is obtained from the carboniferous rocks in the neighbourhood of Edinburgh. The colour is lightish grey, and the grain fine. The cement is siliceous. It contains 98 per cent. silica. The beds vary in thickness, the thickest being ten feet. The number of workable beds is very large. A cubic foot of the stone weighs 146 lbs., and absorbs four pints of water. It resists crushing weights to the extent of 5,800 lbs. to the square inch. It darkens by exposure to a smoky atmosphere and frost. It is an expensive stone. Other coal grits are good, but not equal in colour or composition to Craigleith. Stones from the old red sandstones, on the east coast of Scotland, are dark-coloured and flaky, but hard, and resist atmospheric action. Of these Dundee stone is dark-brown, owing to the presence of iron oxide. Arbroath is greenish grey; not objectionable. Very large blocks of uniform appearance may be obtained, for building and pavements. Yorkshire sandstones of the millstone-grit series are durable both for building and paving. The Stenton quarries, near Durham, have supplied good stone. The Park-spring stone, from near Leeds, and others from the neighbourhood of Halifax and Huddersfield, are good. These may be described as fine-grained stones, cemented with argillaceous cement, coloured by oxide or silicate of iron, the colour varying from bluish green to pale brown. They weigh about 145 lbs. to the cubic foot, and support a crushing weight about equal to Craigleith; but they absorb water readily and part with it freely, and are apt to peel when placed in walls. They are unsafe when in contact with damp earth, or where there is no circulation of air. Sandstones of the lower new red sandstone series, consisting of fine siliceous grains with magnesian-calcareous cement, are quarried at Mansfield, in Nottinghamshire. There are two varieties; one red, weighing 148½ lbs. to the cubic foot, and the other white and heavier. Both are absorbent, taking up from four to five pints of water to the cubic foot. They wear well, but are not safe in a moist, smoky atmosphere. At Liverpool much stone from this rock is used. A sandstone of the lower secondary period, better than most of the varieties from contemporaneous beds, is worked near Whithy, in Yorkshire, and largely exported. Of other sandstones, those of the Wealden period are irregular in their composition and easily acted upon by weather. Some of the sandstones of the cretaceous series are better. The Godstone and Maidstone fire-stones and the Chilmark siliceous limestone are very valuable for certain purposes. Chilmark is rather a siliceous limestone than a sandstone. It is heavy and non-absorbent. Sandstones, consisting of detached grains of indestructible material, cemented to-

by some foreign substance that has been held in depend on the nature of the cementing medium in durability. Where this is calcareous or marly, in irony, it is affected by weather, but where lioeous it is safe. When sandstone is laminated, nters and ultimately produces disintegration. Many nes, ill-adapted for external walls and facings, are as slabs, either for foot-paving, curbs, or other pur-and also for party-walls. Limestones are better for y construction than sandstones; they are more rked, and therefore cheaper, more varied in and appearance; the useful kinds are more ly distributed and the colour is more pleasing. d, Bath, Ketton, Barnack, and Caen varieties are known limestones in London and its neighbour- Their properties are very different. Many other e in local use, some from the carboniferous series alurian rocks. Even chalk is used occasionally ervative purposes, in the interior of buildings. d stone is the hardest, the least absorbent, the ble, and the most resembling marble of all ilding materials. The upper member of the is in England, wherever it is developed, contains nds of shelly limestone, partaking of that racter which has been long known as oolite d. Some of these bands which are least shelly ble building stone. The upper members of d series pass into the Purbeck series (which e "Purbeck marble"). Portland stone is heavy, g from 135 to 148 lb. to the cube foot. It absorbs 4 pints of water per cube foot. It is composed of ent carbonate of lime, with rather more than 1 t of silica and carbonate of magnesia. It can be d in blocks of any size, and can be worked either chical or the plate saw without difficulty. It is, r, expensive. It bears a pressure of 3,279 lb. r crushing. The heavier beds are the most durable r architecture, but the upper beds, or roach, are d for some purposes, especially docks, piers, and ydraulic works. The roach is less oolitic, and its ing medium more perfectly crystallized than the e same, and it resists alternations of dryness and e; but is less sightly, and could not be trusted in d situations in the air. The best quarries of Port- are on the eastern side of the island. Bath e next in importance to Portland, and their cheap- y of working, abundance, and pleasing appear- e caused them to be adopted throughout the d England, wherever they could be conveyed at e. There are numerous quarries, and the quali- e a good deal. They occur at intervals in a series d thickness is from 60 to 120 feet. The series e follows:—

rag stones.....	thickness 25 to 50 feet.
freestones or building bed	" 10 " 30 "
rag stones.....	" 25 " 80 "

is of a rich cream colour, and so soft that it eally be cut with a tooth saw. It is lighter than d, weighing 123 lb. to the cube foot. It is e, taking up 8½ pints of water to the cubic foot, e more than one sixth of its bulk. It bears a crushing t of 2,000 lb. per square inch of surface. The upper e is coarse, shelly, and irregularly-bedded, and e no workable beds. Immediately below are fine- d building beds. The lower ragstone includes e well-defined shelly beds, resting on the Fuller's e. The importance of determining the geological e of the freestone beds renders this identification of e lower and upper ragstone important. The lower beds e the appearance of fine-textured oolitic limestones, e singularly liable to injury from exposure. At Box d Cornham quarries they are 40 feet thick. Bath stone e very rapidly, but by allowing the surface to harden e much improved. The consumption of Bath stone e the present time exceeds 100,000 tons annually.

Caen stone resembles Bath in colour, texture, and facility of working. It weighs 120 lb. to the foot cube, and its resistance to crushing weights is superior to Bath. It is also harder and less absorbent. It is obtained near Caen, with other stones from the neighbourhood, of inferior quality. These are extensively used. Only small blocks of the best qualities can be obtained. Buckingham Palace and several London mansions were built of poor Caen stones. All these stones are remarkably pure and not very shelly. The carbonate of lime is sub-crystalline, and threads of calc spar traverse the stone at intervals. The inferior oolites yield good building stones in the west of England, but they are not superior to Bath stone. Barnack, Ketton, and Ancaster are midland oolites that have reputation; the first named is now replaced by stone from the Casterton quarries. This stone is of a lightish brown colour and compact oolitic structure, and is made up chiefly of fragments of shells and corals. It is heavy, weighing more than 130 lb. to the foot cube. Its resistance to crushing weights is not more than 1,500 lb. Barnack stone has been used in Cambridge, and also in Suffolk. Casterton is believed to be equally good. Ketton stone is brought to London, and some modern buildings of it seem to stand well. Its colour is warm cream. It is lighter than Barnack, and rather superior in resistance to crushing weights. Ancaster is superior in some respects, and equally durable, but has not been much used in London in important works. All these stones are absorbent, taking up about one-sixth of their bulk of water. They are expensive to work as compared with Bath stone, but considerably cheaper than Portland. Excellent oolitic building stones, of bluish tint and fine grain, are found and worked in Yorkshire for engineering purposes. It is not easy to ascertain the value of oolites. In the quarry or immediate neighbourhood they wear well, but when removed, and used carelessly, they resist frost very badly. The number of quarries is large, and the stones of the adjacent quarries are by no means of the same quality. Careful selection is necessary, made with a knowledge of the peculiar properties of the stone. Thus some coarse stones absorb little water, while others, far superior in appearance, suck in water like a sponge and soon decay. In quarrying the oolites, operations are carried on resembling those required for mining; but as large blocks are the most valuable, some difficulties arise which do not occur in mining. In working for stone, it must first be decided whether the stone is to be reached by drifts or by open cuttings. If there is a thick covering of upper hard beds, open quarrying is impossible, and in that case the work is carried on by tunnels. Open quarries, however, are common enough, but there is always a large quantity of waste material, whose removal is a matter of consideration before opening a quarry. In getting Bath stone the quarryman commences operations at the roof, picking it out six or seven feet back. The width of the stalls depends on the nature of the stone. The stone is afterwards cut with a saw, and removed with great care. Besides the limestones used for building purposes, at Bath there are also bands of more compact stone fit for roofing and paving. These flags are inferior to those found in Yorkshire, and to the slates from Cumberland and Wales. Stonesfield slate is one of these. The evenly-splitting flaggy structure is the only important fact. Lithographic stones are worked in large quarries in Bavaria. They are in thick beds, and are remarkable for the extraordinary smoothness and fineness of grain of the surface, and its delicate cream colour. They belong to the upper division of the oolites. Other lithographic stones of inferior excellence are obtained from liassic limestones. Limestones of the tertiary period are not met with in England, but excellent qualities are worked in various parts of the Continent. In and around Paris the limestones of the older tertiaries are opened in extensive quarries, from which the capital is supplied. The stone is of good colour, even texture, and easily and cheaply worked, but does not resist perfectly even the

comparatively pure and dry atmosphere of Paris. Chalk becomes hard and adapted for building purposes in the south of France, and hard white cretaceous limestones are found throughout the middle and south of Europe, available for construction. Many of these are compact and very durable. Compact carbonates of lime in England are chiefly members of the carboniferous series, and pass into marbles. Good lias supplies compact material, usually argillaceous, but the middle beds or "marlstone" yield a limestone. All the stones are absorbent, and are rapidly injured by exposure to moist air in changing temperatures, and especially when there is frost. Magnesian limestones occur in the middle and north-east of England. They consist of a variable proportion of carbonate of lime and carbonate of magnesia, and have been used in recent important buildings in London. Their colour is light brown, of warm tint; their density is greater than that of the oolites; the labour on them is intermediate between gritstones and Portland, and they can be obtained of any required size. They are four times stronger than Portland; certain parts of Derbyshire, Nottinghamshire, and Yorkshire, yield this kind of stone. It was used for the Houses of Parliament and the Museum of Economic Geology in Jermyn-street. The stone in the latter building is extremely good. It is well known how great is the failure in the other building. Whether from more trying exposure, or from the quarries ultimately worked not yielding stone like the sample, it is too late to discuss. The best magnesian limestones are those in which there is at least 40 per cent. of carbonate of magnesia and 4 or 5 per cent. of silica. But the composition alone is of less importance. Where this is complete the stone resists attack, but it is an unfortunate peculiarity of the admixture that it is never the same for many yards together, even in the same quarry. It is desirable to obtain a test of the relative value of stones to be used for building purposes. An attempt was made by M. Brard to determine the relative durability of limestones and sandstones having calcareous cements. This method consists of boiling small cubes in a saturated solution of Glauber's salt (sulphate of soda), and exposing the cubes in the air. The effect of expansion by the efflorescence of the salts, as the water evaporated, tested by weighing the amount of material removed from the stone in a given time, measures the effect of frost. It has not been found that the result can be depended on for practical purposes on a large scale, and it is now seldom resorted to. Slates belong to argillaceous minerals, and are completely metamorphosed so as to have lost all external marks of mechanical origin. In them bedding is replaced by cleavage. They split into thin plates, in planes parallel to each other, independent of original stratification. Those that split into the thinnest plates are used for roofing purposes, and those which yield slabs, for paving and walls. Slates of good quality are not very common, and unless accessible by sea, and there are means of getting rid of the rubbish resulting from the workings, they cannot be quarried with profit. They are limited to certain veins of comparatively small dimensions, in the midst of a considerable mass of schistose rock. Slates are generally from rocks of very ancient geological date, but this is not invariable. The best slates in the London market are obtained either from North Wales, from the north coast of Cornwall, from the west coast of Scotland, or from Valentia, on the coast of Ireland. Very good sorts are found in France, in the Ardennes, in Western Germany, and in the east of Europe. America also yields supplies. Slate hardly weathers when placed horizontally, unless exposed to foot-wear. In the better qualities of slate there is little or no pyrites, and the veins and joints are so arranged as to assist in the working. The best slates are obtained from some depth within the quarry, and in valleys rather than on hills. Exposed and weathered slates seem to have lost much of their fissile properties. All stones are injured by long exposure to the weather;

and in considering the best method of keeping back decay, the composition and state of aggregation of the rock must enter into calculation. The causes of decay are partly chemical and partly mechanical, and include—(1) the action of rain-water, either by friction or dissolving parts of the stone; (2) disintegration of the stone by the action of frost. Rain-water again acts in two ways, decomposing by acids or disintegrating by efflorescence. All deserve consideration, and depend on the absorbent nature of stones. It is by capillary attraction that water is sucked into stones, and there are limits to this attraction. Together with the water its contents enter, but are left behind near the surface. When evaporation takes place from the surface, it is only the pure water that passes off. The foreign substances are left behind, and produce their effect in time. Rain-water contains carbonic acid gas and ammonia, and, however small the proportion may be, everything that can be affected by these substances will yield in time. Thus, even in granite, the silicates become decomposed and the felspar destroyed by the constant action of rain-water, and when the felspar is gone the rock will become rotten. Such is the case in the islands of Alderney and Jersey, in the British Channel. But if granite is destroyed, much more so are sandstones with calcareous cements and limestones. Owing to the quantity of coal burnt, and the impurity of the coal, there is always a certain proportion of sulphurous acid in the air in towns, and this becomes dissolved in the rain as it falls, and rapidly affects the carbonates of lime. This action going on every day, with every change of weather, the surface of the stone, bruised by the action of the tool, and deprived of the only protection nature is able to give, very soon disintegrates. The less homogeneous the stone, the more injured is it by this kind of action. The disintegration by the action of acid vapours would be slow were it not for the alternate expansion and contraction of the moisture contained in it. And this result is obtained in its maximum when the stone is so placed that the moisture is nearest the surface, which will happen when the stone is placed at right angles to this natural direction. Great care should therefore be taken by the builder to place the stones as nearly as possible in their proper position. The injuries that take place in absorbent stones from chemical reactions, are not easily traced, but are not inconsiderable. The various substances accidentally present in stones may become changed by the chemical action of salt contained in the absorbed water, and thus injure the stone and increase its tendency to decay. Many stones suffer efflorescence due to this cause. Loamy clays, places where sand has been used in mortar, or where salt can in any way have been absorbed, and stones in which an unusual quantity of organic matter is present, are liable to this cause of mischief. Efflorescence, from whatever cause, is certain to bring away detached fragments of the stone loosened by weathering. Whatever be the cause of the destruction of stones, it may generally be traced to the absorption of moisture, and thus any contrivance that will check the admission of water will be the most likely to succeed in preserving the material from decay. Many such contrivances have been proposed; they all involve some of these principles:—(1) closing the pores of the stone by some kind of paint; (2) coating the stone by some insoluble mineral substance; (3) defending the stone by causing it to absorb a chemical solution, which, on the application of another solution, becomes decomposed and deposits within the stone an insoluble coat. Paint, by preventing the absorption of water, preserves stone so long as it remains undecomposed. In London this hardly amounts to three years. The injection of oily and fatty matters acts in the same way and lasts only a little longer. There have been cases, where the exposure is not severe, and where the treatment has been adopted before the absorption of moisture, where the result has seemed permanent; but for buildings intended to last, such treatment is useless, as it can only stave off the evil day for a time comparatively very short. About

twenty years ago Professor Kuhlmann applied fluid silicate of potash to harden chalk and porous stone. On soaking chalk with the fluid silicate, a change took place, the face of the chalk becoming converted into silico-carbonate of lime. In practice, this method failed when applied to buildings, because the weather cannot be depended on, and a dry atmosphere is needed during the whole period of hardening. Not long after this had been done in Germany, Mr. Frederick Ransome, of Ipswich, attempted to deposit an insoluble wax, by means of another solution, which should act by double decomposition. He found that by following the silicate by a dose of chloride of calcium the chlorine parting from the calcium attacked the soda of the silicate, forming common salt, while the silicic acid combined with the lime and formed with it silicate of lime, a mineral nearly insoluble, very hard, and adhering with great tenacity to foreign substances. The effect of this treatment on stones that have not already been inserted into buildings has been very favourable, but applied on a large scale to buildings that have already shown symptoms of decay, the result is less satisfactory. A combination of Kuhlmann's process with a temporary wash of bituminous substance, has been tried on the Houses of Parliament by M. Szerelmy. It remains to be seen whether this result will be more satisfactory than that of Mr. Ransome. Besides the varieties of schist and slates used in construction, there are slates loaded with hydro-carbons to so great an extent that the rock will take fire on being exposed to heat and flames. Such rocks are generally called *bituminous shales*. They occur in rocks of all ages, are of various thickness, and exist under very different conditions, but in a general way they may be regarded as clay bands in sandstone rocks, into which a large infiltration of hydro-carbons, and occasionally much iron, has taken place subsequent to the deposit of the rock. Till lately these shales have been of little value, and have attracted no attention for commercial purposes, only those being valued in which the iron was sufficient to enable them to be used as ores of iron. Since the manufacture of illuminating and lubricating oils has been carried on, such shales as yield a sufficient percentage of oils on distillation to be worth working are among the sources of mineral wealth in the neighbourhood where they occur. From the tertiary rocks we have the paper-coal, used for distillation in some works nearly opposite Bonn, on the Rhine. From the cretaceous beds other shales have been worked, though to no great extent. The oolites are richer in bituminous strata. In the Kimmeridge clay there is a band of highly bituminous shale, of dark brown colour, and without lustre, burning readily. Part of it is called "Kimmeridge coal." The lias is richer in shales of the kind, and the "Posidonia schist" has been brought into use for distilling in Wurtemberg. It is chiefly rocks of the carboniferous series that yield the richest of these deposits. In Scotland, near Edinburgh, there are varieties of coal that pass so nearly into shales, and shales that so accurately put on the characters of coal, that it becomes difficult to distinguish between them. The well-known Boghead coal, and the Torbane-hill mineral are examples. These are either shales or coals, according to the line that may artificially be drawn between coal and shale. They are rich in the products given off by distillation at a low heat, and are ill-adapted for fuel. Many other minerals, departing more widely from coals in appearance, are called in Scotland "parrots," or crackling coals, and in England "cannels." When once set on fire they burn freely, with a bright flame and much smoke. They are easily distinguished from coals, but are more valuable than coals themselves for distilling. In the coal-fields of Lancashire, North Wales, and the Potteries, many such bands have been recognised. Some of them are rich in iron, and the iron stones of these and other coal-fields, including the "black band," are highly bituminous. The bituminous shales hitherto made use of in England are almost entirely from these black and brown bands in the coal measures, but this is not the case

elsewhere. In the east of France, near Autun, not far from Dijon, there has long been a large manufacture of oils distilled from schists, quite independent of the coal. They have no resemblance whatever to coal, but one of them resembles the Scotch Boghead. Other cases exist in the west of France, where similar shales have been distilled. Good bituminous shales rarely soil the fingers; they are brown when scratched with a sharp point, and they break with an irregular fracture. They are usually tough, and sometimes fissile.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 1st, 1865; Rear-Admiral Sir Edward Belcher in the chair.

The following candidates were proposed for election as members of the Society:—

Dibley, George, 72, Malden-road, Haverstock-hill, N.W.
Miles, Henry Thompeon, 61, Strand, W.C.
Redman, Capt. Gabriel J., 6, Belsize-park, Hampstead, N.W.

The following candidates were balloted for and duly elected members of the Society:—

Reeves, Miss Sarah, Rectory Grove, Clapham, S.
Ridley, Rev. N. J., Hollington-house, Newbury.
Templeton, Archibald, 16, Argyll-road, Kensington, W.
Templeton, John, Budge-row-chambers, E.C.
Wallace, Hugh, Chemical Works, New-road, Battersea-park, S.

The Paper read was—

ON THE MEANS EMPLOYED IN TAKING FISH, ESPECIALLY WITH REFERENCE TO SUBMARINE ILLUMINATION.

By F. W. CAMPIN, Esq., BARRISTER-AT-LAW.

Although to the fisherman's calling there attaches a special feeling of interest, arising from the fact that some of the most notable of the first Apostles of Christianity were fishermen, and that we have in the Holy Scriptures narratives as to their labours in pursuit of their temporal calling, yet, whilst nearly every other industrial avocation has received attention and undergone modification, improvement, and advancement at the hands of our inventors and improvers of useful arts and trades, very little has ever been done to improve that of the fisherman; hence it seemed to me desirable to endeavour to direct public attention to the real state of the case, with the view of demonstrating that there are now available, means and appliances by which fishing operations can be rendered more easy, safer, less destructive to the breed of fish, and more productive than the methods and means heretofore employed.

It is true that in former times public attention was much directed to the promotion of this branch of industry; but this promotion took the form of Acts of Parliament, passed both in Scotland and in England, granting special immunities and supposed advantages to persons engaged in fisheries; and the herring fishery in particular was guaranteed much of that kind of encouragement which was then in vogue, viz., the institution of monopolies and special privileges, though it appears that a somewhat sounder measure was brought forward when, in 1677 (King Charles the Second's time), a new royal company was established in England, at the head of which were the Duke of York (afterwards James the Second), the Earl of Derby, and other influential persons. This company, after being favoured with considerable success, was brought to an end by an unforeseen and untoward event. Most of its vessels, termed "busses," had it appears been built in Holland and manned with Dutchmen, and, on the pretence that these were Dutch vessels, the French, who were then at war with Holland, seized a number of them,

and this, it is said, ruined the company. Attempts were afterwards made to revive the undertaking, but they came to nothing, the death of the king intervening. Soon after the Revolution this business was again resumed, and efforts were made to interest the public at large in the scheme, which do not appear to have been successful, as we have no further accounts of the matter. Since that time other attempts have been made to encourage our sea fisheries, as in 1749, when an association (the "Society of the Free British Fishery") was formed, and bounties were granted to all vessels employed in the fisheries; but it was found in the end that the Dutch kept the market, although in 1757 the bounty was made up to 66s. per ton. However, little has ever been done in the right way, viz., organization and improvement of the art of fishing and of the methods and appliances used in the art, though it ought to be here recorded that the Society of Arts gave much attention to the subject of increasing the supply of fish, and that it was due to the exertions of the Society and the rewards it offered, that the fish-vans or fish-machines used (until the railway system became developed) for speedy transport of fish from the coast to London were adopted. Further endeavours were made by offers of prizes to stimulate the supply of large fish, such as turbot of a certain size.

Before leaving this part of the subject, it may not be amiss to briefly allude to the importance, in a national point of view, of maintaining and improving our fisheries, as to which it has been well observed, that since "Providence hath so eminently stored the coasts of Great Britain and Ireland with the most valuable fish, and since fisheries, if successful, become permanent nurseries for breeding expert seamen, it is not only due to the Supreme Being not to despise the wonderful plenty he hath afforded us by neglecting to extend this branch of commerce to the utmost, but it is a duty we owe to our country for its natural security, which depends upon the strength of our Royal Navy. No nation can have a navy where there is not a fund of business to breed and employ seamen without any expense to the public; and no trade is so well calculated for training up these useful members of society as fisheries." Since the repeal of the Navigation Laws this point has become of greater importance than ever.

The situation of the British coasts has been said to be one of the most advantageous in the world for catching fish; the Scottish islands, particularly those to the north and west, the most commodious for carrying on the fishing trade to perfection; for no countries in Europe can pretend to come up to Scotland and Ireland in the abundance of the finest fish with which their various creeks, bays, rivers, lakes, and coasts are replenished. Of these advantages the Scots seem indeed to have been most abundantly sensible, and their traffic in herrings is noticed in history as early as the ninth century.

The ordinary methods and appliances used for fishing purposes are, it seems, these:—

Cod-fish, as a rule, are taken by means of hand-lines but at the approach of autumn and in winter, when the fish are at the lowest depths seeking "ground bait," long lines have to be resorted to, which are furnished at intervals with hooks, upon which wilks are fixed for bait, and these are sunk by being "shot," or paid out, and after lying nearly a day or a night are "payed in," and the fish, if any, are taken off and put into the well of the smack. In fine weather small cod-fish are sometimes swept into the trawl net, the trawl beam, to which the net is fastened, mostly dragging the bottom, which is very injurious, destroying young fish and ova; in fact, so great is the evil of this, that it is now under investigation by the Royal Commission appointed to inquire and report as to British fisheries.

Mackerel are taken at one season with nets constructed on purpose, as, being then blind, any bait which may be lowered can be of little avail, as it cannot of course be seen by them; but after this blindness has left them hand lines are employed.

Whitings are taken by hand-lines baited with mackerel, from April till August. They are taken by trawlers in great numbers; but, when caught by trawling, their market value is much lessened, by reason of their scales being rubbed and the elegance of the fish destroyed; whereas, by the ordinary line-fishing they are not damaged, and they fetch a high price in consequence.

*Haddock*s are taken by lines with mussels for bait, and are also taken by trawling, but are then, as is the case with whitings, very much lessened in value.

Gurnets are generally taken by lines, and frequently while fishing for whitings.

Skate are very frequently taken by the hand-lines, the same bait being used as for cod. They are also at times swept into the trawler's nets; many are taken on the Doggerbank fishing grounds by the long lines.

Artificial baits are sometimes used, and are made of vulcanised india rubber—hollow—and in the form of a fish. They have been tried in several instances and found to be highly attractive. They are made by W. Warne and Co., of Tottenham, and are, for the following reasons, very economical: Being exceedingly tough, they are not destroyed by the teeth of the fish; entering crosswise, they are not swallowed, and are usable a second time; they are at all times ready for putting into the hooks, and can easily be taken off when out of use; wilks, being the chief bait for cod-fishing, cannot always be obtained—smacks often lose days waiting the arrival of wilk-boats, and wilks once used are mostly destroyed; besides all which, many are found to be dead when wanted for use; and such is the extraordinary facility these fish (cod) have for scenting dead wilks, that they instantly reject a "dead un." Taking all things into view, the artificial baits are, perhaps, more economical and advantageous than any other kind of bait.

It is a well-known fact that fish are to be attracted by light—a fact which was not unknown to the ancients; and it has been the constant practice of the Chinese, handed down from remote ages, to use apparatus for catching fish, consisting, as I understand, of a board or frame, having candles or other means of lighting placing thereon, with a frame or net hinged thereto, which is floated on the surface of the water, and when the fish have been attracted by the light to the frame or net it is thrown up on the hinges, thus taking the fish. Surface lights have also been in use for catching salmon, pilchards, and other fish. An attempt to render a surface light commercially available was made by a public company about the year 1826. It was not, however, persevered in, and I am not aware that its operations were attended with any degree of success.

In the year 1862, Mr. Henry Richardson Fanshawe obtained a patent for "improvements in the mode and means for fishing in seas, rivers, and other waters;" and in the specification of his patent he thus describes his invention:—

"My improvements consist in the employment of a submerged or subaqueous light, for the purpose of alluring or decoying fish, thereby facilitating their capture, the light I employ being derived from electricity or from the ignition of oil or gas, or I may employ phosphorised oil or other luminous fluid or any means for producing or maintaining a light under or below the surface of the water; or I may obtain a sufficient volume of light for my purpose by reflecting light from above upon submerged reflectors."

Mr. Fanshawe further states that he uses "arrangements of globe, lantern, or reflectors, the decoy light or reflector being placed or disposed in such a manner at the required depth that the fish are attracted thereto by the light. The illuminating apparatus may be lowered to the required depth by any mechanical arrangement which will answer the purpose desired, but he constructs or fits boats with a well or walls at or near their centres, for the purpose of more conveniently superintending the working or adjustment of the decoy arrangement, and of seeing

when a sufficient number of fish are collected, so that the boat may be removed for the purpose of closing the net or nets. When the electric light is employed, the lantern may be sunk before ignition, and the light extinguished before its withdrawal."

After describing in detail the invention, Mr. Fanshawe's specification states:—

"In working the boat with the lantern and its lowering apparatus, I place it in the position assigned by previous arrangement with the fishermen, and having unbolted the top of the lantern and ignited the lamp, re-bolted the top on, and connected the two lengths of flexible tubing required, one to the inlet and one to the outlet pipe, I lower the lantern, by means of a windlass and chain, to the desired depth; this, in many cases, will be found to be about half the depth from the surface to the bottom. It will be obvious that tubes must be of such a length that, at all depths to which the lantern may be lowered, their ends may be above the surface of the water, and I prefer to maintain them in a position about eight feet above the surface of the water, bending their upper ends downwards to prevent water and spray from entering, and the wind from disturbing the current of air in the apparatus, as it may otherwise cause too great pressure on the ingress, and impede the escape of the bad air from the outlet pipe. In some cases the light may be required to be stationary, in others it may be found advantageous to move slowly in any one particular direction as may be previously agreed upon. In working or manœuvring the well boat and lantern, much must depend upon the nature of the bottom, the depth, and also the habits of the particular fish sought after, which will be best known by experienced fishermen. When a sufficient time has elapsed for the fish to congregate in the locality of the light, the boat can (after drawing up the lantern and air tubes) be moved, in order to enable the fishermen to carry out their operations.

"In line fishing similar operations are carried out, always taking care that the baited hooks are placed in a horizontal, or nearly horizontal, line, and to employ the reflector lanterns, as hereinbefore mentioned, so as to throw the light in the direction of the line or lines.

"In some cases, where it may be found desirable to employ more than one lantern, a buoy or buoys should be used to sustain the lanterns, and the tubes supported by a frame of wood or metal fixed upon the said buoy, the ends of the tubes being carried about eight feet above the buoy, and bent downwards, as in the case before mentioned. To assist in maintaining the steadiness of the light, which, when in use as a decoy, is important, I employ a strap or band of vulcanized india rubber between the end of the windlass and the ring on the handle of the lantern. This strap or band must be of sufficient strength and length to prevent, as far as possible, the communication of the undulating motion of the boat or buoy to the lantern by the extension (due to its elasticity) of the said strap or band. I protect the said strap or band by placing a chain or chains, of greater length than the said strap or band, in such manner that the chain or chains will hang loose, and upon any sudden snatch, or motion on the surface of the water, the chain or chains will limit the extension of the strap or band, and prevent its breakage. In moderately-smooth waters the use of this strap or band will not be necessitated.

"In all cases where india-rubber tube is mentioned in this specification, it should be understood that it must be vulcanized india rubber tube, and must be of the description known as suction tube; and in all cases where glass is mentioned, the glass may be either plain or coloured, in any way that may be found to give the tone of light best suited for the purposes herein described, and for the particular kind of fish sought after.

"In some cases I employ a mirror or polished surface to act as a reflector of the sun's rays, or at night to reflect those of the moon, or of lamps or lights placed superficially above the water; and by means of cords or chains

hereinafter mentioned, I regulate the angular position of the upper rays of light, whether of natural or of artificial light. It is found that in very clear water a lantern, similar to that termed a bull's-eye lantern, produces from the side of the boat or vessel a strong reflected ray of light upon the submerged reflector, but the plan of employing the reflectors answers well in very clear waters only. When the bull's-eye lantern is employed, the reflector therein should be placed higher, and at a more acute angle than is the case in the common bull's-eye lamp, and the lens should be placed at the corresponding angle, so that there may be no necessity to interfere with the upright position of the wick or lamp. The reflecting submerged surface must be weighted, and have cords or chains as, hereinbefore-mentioned, leading up to a boat, and fastened to the gunwale, or to pegs or hooks."

Mr. Fanshawe made the first sea trial of his invention in May, 1864, in Rye-bay, on the fishing ground known as the Falls, and was very successful in decoying whiting and mackerel to the bait. As in most first trials, some difficulties presented themselves. From there being too little weight to sink the lantern and to keep it perpendicular in the under-currents, and also in consequence of the prevailing E. and N.E. winds, not so much success attended these efforts as was expected. However, a trial was made in August, off the coast of Scarborough, where, upon one occasion, several gentlemen of that town accompanied the *Heavit* smack to witness the effects of the Patent Subaqueous Light, and were, as they expressed, equally surprised and delighted. A report was published in one of the papers of that town. Many of these gentlemen were provided with their own lines and hooks, and took large quantities of whiting.

The appearance of the sea during this trial has been described as very splendid—the reflection from the sunken light throwing up the bluish green tinge of the water from the valley to the crest of each wave. Even the sails and cordage of the vessel were thus lighted up with the resemblance of a ship afloat on a sea of gold. The silvery fish darting about, and ever and anon ascending nearly to the surface of the illuminated water, presented the appearance of dots of polished silver in a sea of gold and azure.

In the five voyages made by the above-named vessel, in which the light was placed, many whiting were taken to market. In fact, the experiment was deemed a most successful one.

In September, 1864, the smack *Heavit* again left, but this time for the North Sea fishery, to take cod-fish by the aid of the subaqueous illuminator, and was very successful upon several occasions. She was accompanied by other vessels, which also were successful in taking cod-fish in the illuminated water, the largest quantities of fish being found at the verge of the light, or rather in the shadow, as many as thirteen score having been taken at one "take" by a smack so placed. As a rule the largest and finest fish are taken nearest to the light, the smaller and more timid fish being in the shade.

Oil lighting material has so far been employed, and there is no doubt that eight or ten fishing vessels could be worked round one light, especially if one of greater intensity—such as the electric light—were adopted.

Although Mr. Fanshawe's patents, both for Great Britain and for France, for the application of light to fishing purposes, were secured prior to the patent of Iodocetus, whose name has been before the public in connection with this subject, he has most successfully used the electric light on the French coast, and under, it is said, the especial sanction of the French Emperor, has captured large quantities of fish, showing at once the certainty of the principle adopted, namely, that fish are unmistakably drawn from the ground, at sea or in rivers, by the decoying action of light. The great object gained by the subaqueous illuminator, is that we descend so near to the fish as to induce them to leave and to take the bait, which is visible, whereas surface lights, when employed,

are only useful as decoys in isolated cases, and then only to a very inconsiderable depth.

As an instance of the magical effects of light upon fish, it is stated upon reliable authority that in cases where the diving bell has been employed in vicinities where fish are to be found, the water immediately around has been seen teeming with them.

The subaqueous light was tried in fresh water in the River Lea, at Tottenham Mills, and was visited by very many persons. The attractive properties were at once manifest, greatly to the admiration of the many people present. These displays took place during a period of several months, and previously to the display of the principle in salt water.

Mr. Fanshawe proposes to employ the light in fresh water for salmon-taking.

Mr. Fanshawe's system is said to be very advantageous for the following reasons:—

1. As economising labour on the fishing grounds.
2. Shortening the time now occupied in taking any given number of fish.
3. In the quantity of bait used, and in the necessary outlay for lines and gear—"long lines" being superseded—"hand lines" only being required in line fishing.
4. Increased safety for human life, the work being confined to the decks of the vessels.
5. In the conservation of the young fish, too small for market, and also of the ova; there being in ordinary trawling (numerically) more fish destroyed by the present trawler's "beam," and the necessarily great pressure of the "long lines," than are caught. By the patent decoy light this constant process of destruction of newly hatched and of unhatched fish is entirely obviated, as only fish worth taking rise from the bottom to the decoy light, and are there taken by the baited hooks; or, as in the case of trawling, within the range of the usual nets; trawling as usually practised being superseded.
6. Increase of fish supply. Independently of the advantages shown by the employment of this patent plan as regards the extra quantity of fish caught through its aid, there are many localities inaccessible to the ordinary modes, and whence fish may be decoyed to more favourable positions for capture; besides which, immense quantities of non-edible fish are attracted, all of which are valuable, either as manure, or as oil producing material; and these fishes are voracious, and constantly feeding upon the edible fish, so that two ends are gained by their removal.

In concluding this, my imperfect essay to handle a subject doubtless second to none in national and commercial importance, I may perhaps be allowed to state that I have abstained from treating of the taking of fish by angling, as that is a method resorted to more as a sport or pastime than as a matter of trade, this latter being as it appeared to me what needed consideration. Further, it perhaps may be permitted to me to state that I have practically no acquaintance with fishing operations, all the statements that I have made on that head being derived from information obtained from Mr. Fanshawe and others; and in alluding to that gentleman, I hope I may be allowed to trespass further on your time, by referring to an incidental topic—one as I conceive of the very greatest importance—it is this:—that should Mr. Fanshawe's invention be found to be an improvement of public and commercial importance—it is without question one by which he would have no chance of obtaining any pecuniary remuneration, unless it were by interesting capitalists in the formation of a company (which I understand is his intention), securing them in the possession of the exclusive rights granted by the patents, or by the means of royalty payments for licenses under the patents; in other words, without the patent laws, Mr. Fanshawe would have no chance of reward.

DISCUSSION.

Mr. STOVIN remarked that during the reading of the paper the question had been asked when this patent was

taken out, and no doubt the length of time which had elapsed since the filing of the specification (1862) might, if unexplained, tend to throw some discredit upon the invention. The delay in the commencement of the operations was easily accounted for. In the first place, there were great difficulties attending the organisation of a system to carry this invention into practice, a great many experiments had to be tried, and various kinds of apparatus had to be constructed before that which would thoroughly answer the purpose was arrived at. Then again, Mr. Fanshawe himself was so much occupied with other business that he could not give his entire attention to this matter, and therefore it had been put off from time to time, and though experiments had been tried at intervals, they had not been carried on in such a manner as to attract public attention to the invention. From what he had seen of it himself, he fully believed it was calculated to confer great benefits on the community in the way of increasing the supply of fish to the markets, and cheapening that which might be made a staple article of food, so as to bring it within the means of the poorer classes. He believed that when a company had been formed to carry this invention into practical operation, the results would be of a highly satisfactory character; but, as far as the experiments had gone hitherto, they did not afford a fair criterion on which to form a judgment as to the real merits of the invention.

Dr. BACHHOFFNER (who had inquired the date of the specification) said he asked the question simply from curiosity, inasmuch as he had not heard of it before. There were many points in the system brought forward which struck him as ingenious, but they all knew that the plan of catching fish by alluring them with light was no novelty, though the light was most commonly employed above instead of below the surface of the water. At the same time he must be allowed, on the part of the finny tribes, to repudiate the idea of their being attracted by being enabled to see, through the means of this submersed light, the particular nature of the bait which was offered to them. For his own part he did not believe that fish were such epicures, although, like the moths, they might be attracted by a light to their own destruction. He apprehended that the invention was also applicable to deep sea fishing; and if that were so, he imagined that some means would be required for forcing air down the flexible tube in order to support combustion. The use of submarine light for facilitating operations beneath the surface of the sea was no novelty. At the time of the operations for blowing up the wreck of the *Royal George*, at Spithead, the late Sir Charles Pasley complained of the difficulty of carrying on the works when the water was in a thick and muddy state, when he (Dr. Bachhoffner) suggested that if the divers were supplied with two pieces of artificial graphite in connection with the wires used for firing the charges of gunpowder by electricity, the means of obtaining a submarine light would be furnished. The suggestion was acted upon, and the result was satisfactory, but he did not remember whether it was in that instance that the fish flocked round the divers in such extraordinary numbers. He had heard of an invention for introducing the electric light below the water in a vessel hermetically sealed, but he believed it was only intended for the purposes of submarine foundation works.

Mr. S. REDGRAVE confirmed the remarks made as to the antiquity of the practice of decoying fish by means of lights on the surface of the water. Mention was made in an old work of a lady at Twickenham, who was annoyed by the disturbances made at night by the salmon fishers in the Thames; and he had in his possession a drawing, eighty years old, representing salmon-fishing by torch-light in the river Tamar.

Mr. BISHOP mentioned that surface lights in fishing for salmon and other fish had been in use for many centuries on the coasts of Norway, more particularly on the Naze and at Christiansand.

Mr. VARLEY remarked, that many years ago Admiral Coffin introduced a method of catching fish in large quantities by means of glittering artificial bait, a plan which was particularly successful in mackerel fishing. For such a process he thought the proposed submerged light would be extremely applicable.

Mr. DE MORNAV said, in almost all parts of the world the practice of fishing with lights on the surface of the water obtained. In parts of America large quantities of fish were taken by attracting them in this manner, and then feeding them with a preparation made from the bark of a species of *mangue* tree, the intoxicating effects of which caused the fish to float helplessly on the surface, when they were taken in large numbers. In a short time they recovered, and no pernicious effects were produced in the fish by this drugging, so as to depreciate them as food.

The CHAIRMAN said, as an old fisherman of sixty years' standing, he might be able to tell the meeting a little about the subject under discussion. In the first place, with reference to the remarks in the early part of the paper, that the fishing trade of this country afforded a means of recruiting the naval service, he might say, after a very long association with sailors in Her Majesty's service, that he had very rarely found a fisherman in the navy; and he supposed that was a great deal owing to fishermen being exempted from impressment during the war. It was, however, often the case that old seamen who had served in the navy fixed themselves along shore and became fishermen, but these were worn-out men, and would, of course, be unfit for the service. The only really able fishermen were those in the North Sea, and they were too well paid for their work to enter the navy. As a naval officer, having to select a ship's crew, he would, as a rule, refuse fishermen; and he knew that was also, to a great extent, the feeling of French naval officers. On one occasion he was informed by a French admiral that, being forced suddenly to put to sea, he had been compelled to take a crew mainly composed of fishermen. The result was that he was obliged to reef topsails, and for many days dared not make sail, because his crew of fishermen were all sea-sick and unable to work. During the French war two fine ships sent to sea were captured, within a few miles of the French coast, by two small frigates—an easy conquest, in consequence of a great portion of their crews being sea-sick and unable to fight. The Newfoundland men were great fishermen, but their occupation there was merely to sit within a circular space, with a barrier to protect them from the water, and to clean and split fish, an employment which did not in any way fit them for service on board ship. In the days of his (the Chairman's) boyhood he was in the habit of running away from his home, and spending a good deal of time with the Mic-mac Indians, learning their secrets in fishing. One of the principal methods employed by semi-civilized tribes, as well as by savages, had always been the use of the flambeau at night, and at the present time that mode of fishing was a favourite amusement amongst the ladies of Nova Scotia, the prey being chiefly lobsters, which, being attracted by the light, were taken by prongs into the boat. He had fished in every part of the world, and was bound to say he could not give the preference to our English coasts in respect of the quantity of fish to be taken. It was in Newfoundland, on the coasts of Barbary, and in Southern Africa, eastward of the Cape of Good Hope, that the best fishing was to be found. There was no necessity for bait there; but with little pieces of bright metal, with hooks attached, fish were pulled up as fast as the line could be put in, by what was known in this country as "foul-hooking." On the west coast of Newfoundland a cutter, 25 feet long, would be filled with fish in two hours with ten lines. In the deep-water fisheries of that country lines of 70 fathoms in length were used, and the hooks were baited with the bright metal baits, until the month of June, when the

caplins—small fish resembling the smelt—come in season, and then these were used. A great bait for fish in most parts of the world was the squid, or cuttle-fish. With respect to the delicate taste of fish in their bait, he had not much faith in this, for it was a common practice, after having caught one fish, to take what he had in his stomach for bait, and thus to catch a great many more. It was a very curious fact with regard to mackerel, that in some places the fish did not open their eyes till about the 22nd May, and in other places, such as on the coast of Ushant, in France, they did not bite till the first week in June. The bait most used for taking this fish on our own coast and in the North Sea was the lug-worm. Skate were principally captured with the trawl, but they were occasionally taken by bait in the North Sea. The trawl had of late years, from some cause, got into sad disgrace, and was now on its trial before the House of Commons; but he believed this was mainly due to a quarrel between the fishermen on the north-east coast and the Torbay fishermen, some of whom came to the north-east coast, and understanding the proper use of the trawl better than their brethren there, were consequently more successful in their takes of fish, and hence jealousy had arisen between them. For his own part, he thought the trawl, when properly used, was not open to the objections made against it. On the western coasts of South America the half-caste Spaniards were very successful in fishing with flambeaux, made of long, thin strips of a red resinous pine, bound together in bundles about as thick as the wrist. The boat, with the flambeau projecting over its bow, was kept in gentle motion, and the fish being attracted to the surface by the light of the flambeau, were readily speared in great numbers. In China and the West Indies fishing with lights on the surface was carried on to a great extent, but in this instance nets were used. He had seen fish go to the bait in 32 fathoms water. By throwing a little oil on the water a perfectly glassy surface was obtained, and it was possible to see very clearly to a great depth; and this was particularly the case in some of the lakes of Switzerland. He would now say a word or two with regard to the question of the production, by this invention, or by any other means, of an increased supply of fish as a food for the poorer classes. There were already large takes of fish, such as herrings and mackerel, at Tenby, which (although there was railway communication) it was not thought worth while to send to London or elsewhere for consumption by the people, and if this was so, what was the use of endeavouring to obtain still larger quantities? While the fish was disposed of on the coast at nominal prices, and used for manure, all kinds of fish remained very dear in London, and beyond the reach of the poorer classes. Our great want, therefore, was, that the fishermen should be compelled not to throw away large supplies of food when there was a glut of it in any particular locality, but that they should be forced to send it to market, where there was a great demand for it. It was a well-known fact that, years ago, in order to keep up the price of fish in the London market, the fishmongers stopped the smacks at the mouth of the Thames, and made them throw their cargoes overboard. With regard to the powers of Mr. Fanehaw's patent, it was well known that its powers did not extend more than three miles from the coast of Great Britain. Reverting to the question of the alleged destruction of small fry and ova by the trawling beam, the chairman remarked that he felt quite sure the objection to the trawl arose entirely from ignorance of the proper method of using it, and not from any fault in the apparatus itself. No fisherman, he said, who understood his business, would attempt to draw his trawl against the tide, for he would catch no fish. The boat must go with the tide, but a little faster, and then the trawling beam would rise up some little distance from the bottom, and the best fish would be caught. With regard to the alleged destruction of spawn by the trawl, no spawn was found in deep water. It was a fact well-known to naturalists that the spawning

of all descriptions of fish took place in the shallow water along the shores and creeks, where there was no trawling. The outcry against the trawling on the ground of the destruction of ova was not, therefore, justified by facts. The chairman concluded by proposing a vote of thanks to Mr. Campin for his paper.

The vote of thanks having been passed,

Mr. CAMPIN acknowledged the compliment, and said if he had known that his efforts would have been subjected to the criticism of so experienced an authority as Sir E. Belcher, he should have hesitated in bringing this subject forward, having himself no claims to attention as a practical fisherman. Looking to the project of Mr. Fanshawe he thought, on the whole, some beneficial results in regard to an increased supply of fish as an article of food might be expected from its application. Judging from the remarks of Mr. Stovin, he thought that gentleman was too diffident with regard to the experiments already made, inasmuch as Mr. Fanshawe had reported that his apparatus had been the means of attracting very large quantities of fish. Whether it would be commercially successful or not was a question he would not now enter upon. With respect to the point raised by Dr. Bachhoffner as to the supply of air necessary for combustion at a great depth under water, he apprehended that was a mechanical matter which could easily be provided for, and he believed Mr. Fanshawe contemplated the use of some air pumping apparatus for great depths.

Mr. HAWES said, as Chairman of the Council, he would venture to take the somewhat unusual course of giving the thanks of the Council, and he was sure he might add those of the meeting, to the chairman for having, in so able and entertaining a manner, communicated to them the results of his experience on this subject, extending over a great number of years.

Proceedings of Institutions.

BAOUP MECHANICS' INSTITUTION.—The Report of the Directors, presented at the twenty-sixth annual soiré, January 3rd, 1865, records the continuance of the prosperity of the Institution. In their efforts to promote the cause of education, the directors have received abundant help from friends of every religious denomination, and a spirit of kindly sympathy has been displayed by the members. The finances of the Institution are in a healthy state. The receipts have been £399 15s. 6d., the balance in the treasurer's hands at the end of the financial year being £12 10s. 1½d. In the first quarter of the year there were on the books 276 members; second ditto, 225; third ditto, 200; fourth, 287, being an average of 246 members per quarter. The directors regret that many of the members are in the habit of discontinuing their subscriptions during the summer quarters. The effect of this narrow policy is to cripple the funds of the Institution to a very considerable extent. During the year about 90 volumes have been added to the library. An increase over the previous year has taken place during the last twelve months in the issue of volumes, the number being 7,038, or an average of 41 volumes for every member whose name is on the librarian's register. The news and reading-room is much frequented. The receipts of the Wednesday evening lectures, which terminated in March last, were a little short of defraying the expenses of the course. The third series of lectures and entertainments commenced in October last. Amongst them may be mentioned the Rev. Arthur Mursell, of Manchester, "Wanderings at Waterloo;" Mr. Robert Dodwell, C.E., of Manchester, lecture entertainment, entitled, "Two Hours in a Telegraph Office," illustrated by apparatus, &c.; Mr. Samuel Wimpenny, of Holmfirth, "The Life and Travels of Dr. Livingstone," illustrated; Messrs. Ellis and Cavanah, of the Manchester Shakesperian Society, "An Elocu-

tionary Entertainment;" Mr. W. A. Abrams, of Blackburn, "The Literature of the Lakes;" and Mr. T. Hastings Ingham, of Skipton, "The Philosophy of Shakespear." A manuscript magazine, consisting chiefly of original contributions by members and their friends, was commenced in April, 1864, and has been successfully continued monthly to the present time. It has proved valuable as a treasury of institutional and local information. The character of the evening schools has, during the last twelve months, been fully maintained. The increase in attendance at the evening classes has been considerable. In efficiency, as tested by the Local, Society of Arts, Science and Art, East Lancashire, and Lancashire and Cheshire Union Examinations, the School has made decided progress. It is a source of regret that in some of these examinations the candidates are almost entirely from the younger members of the classes, while the older ones make no attempt to compete in them. The establishment of the science classes, in which chemistry and physiology are taught, has been attended with the best results. The directors regret that the female classes are not so numerous attended as they deserve to be, seeing that they offer a good opportunity for young women to acquire a serviceable education at an inexpensive rate. The day school has been well attended during the twelve months, but as work has been scarce and unremunerative, many parents have not been able to pay the full fees. The number of children on the day school book is 232, and on the night school book 119, making a total under tuition at the Institution of 351.

FARNEHAM YOUNG MEN'S ASSOCIATION.—At the recent annual general meeting of the members, the committee for 1865 were elected. From the balance-sheet it appeared that the expenditure for last year was £134 2s. 7d., the balance due to the treasurer being £29 2s. Several important alterations were made in the rules of the Association. Since this meeting the debt of the Association has been kindly paid off by the Bishop of Winchester, President.

DIGEST OF PARLIAMENTARY PAPERS.

Notice having been given by Mr. William Ewart, in the House of Commons, "To call the attention of the Government to the public advantage which would result and the saving which would accrue from the publication of an abridgment or digest, to be issued from time to time, of all the Parliamentary Blue Books, and similar documents, on the same plan as that of the 'Statistical Abstract' issued by the Board of Trade since the year 1854" (Friday, 10th March), the following statement of facts on this subject may not be uninteresting:—1. The Parliamentary Papers consist of (1.) Votes and Proceedings of both Houses of Parliament, Journals, &c.; (2.) Bills as presented in both Houses, and in their various stages; (3.) Papers presented by command, viz., Correspondence on Diplomatic Subjects—Reports of Permanent Commissions and Public Departments, such as Revenue Boards, Poor-law, Judicial Statistics, &c.—Reports of Temporary Commissions, such as Patent Law, State of Education, &c.; (4.) Returns ordered by both Houses; (5.) Reports of Committees of both Houses; (6.) Acts of Parliament. 2. On an average, there are upwards of 1,000 documents published yearly, the greater part of which are in folio, and altogether they extend over not less than 60,000 pages per annum. The cost of printing papers for both Houses of Parliament was given in 1864 at £67,500, independent of the large amount expended in printing, &c., for the several departments of Government, amounting in all to upwards of £300,000. 3. In the publication of such documents there is necessarily, and in many cases unnecessarily, a constant repetition of facts, a great diffusion of details, and an evident want of system.* 4. Such papers are not much read by the

* In illustration of this fact it was shown in evidence before the Committee of the House of Commons in 1863, by Professor

members themselves, for want of time during the Session to wade through them; nor are they read by the public, for want of facilities for getting at them. 5. Setting aside the sale of these documents singly at the Parliamentary Paper Offices, which is comparatively very small, the public at large have no means of consulting such Parliamentary Papers in a collective form, since, on account of their bulk and expensiveness, no private gentleman and no public institution can conveniently afford the space required to keep them. Apart from the British Museum and other National Libraries (three or four in number), very few other libraries possess a full collection of all Parliamentary Papers. 6. Hence the greater bulk of such Parliamentary Papers, which would be well calculated to diffuse solid and valuable information on all political, financial, and economic subjects, is sold and used up as waste paper. 7. The Committee of the House of Commons on printed papers, of 1835, originated by Mr. Joseph Hume, in their report, p. 24, recommended that the printing committee should have power to classify such papers, and to direct the manner and form of printing the same, either *in extenso*, or by way of abstract, as may be most calculated to convey to the House the requisite information. 8. In 1852, the Society of Arts, and Mechanics' and Literary Institutions throughout the country, petitioned Parliament for the gratuitous distribution of many of these reports, alleging that such a diffusion of useful knowledge would be attended with very great public advantage; and on the motion of Mr. Tufnell a Committee of the House of Commons was appointed to inquire into the expediency of distributing *gratis*, under certain regulations, a selection from the reports and returns of the House of Commons among Literary, Scientific, and Mechanics' Institutions throughout the United Kingdom. The committee recommended that on the receipt of any applications certain reports or papers should be granted. But it does not appear that the resolutions were at any time carried out, from the difficulty of making any selection, and from the want of accommodation in such institutions for such a mass of heavy volumes. 9. In 1854 the Board of Trade began to issue the statistical abstract, comprising a collection of all the facts recorded in all the public documents for the previous fifteen years, and this has been eminently successful, in consequence of the easy reference it affords for a considerable amount of varied information hitherto unattainable except from numerous sources; but the statistical abstract is confined to economical facts, and gives none of the circumstances which give rise to such facts. It only culls out the figures, which, though instructive in themselves, do not sufficiently indicate all the lessons they are intended to teach. 10. Attempts were made to supply this want in 1856 by Professor Leone Levi, in his "Annals of British Legislation," being a summary or digest of all public accounts, papers, reports, &c., of both Houses of Parliament, classified under the following eight series, each comprising all the papers published on the respective subjects:—Series A, Finance, Commerce, and Agriculture; B, Diplomacy and War; C, Ecclesiastical Affairs and Education; D, Railway Shipping, and Postal Communication; E, Law, Justice, and Crime; F, British India, Colonies, and Dependencies; G, Population, Municipal and Parliamentary; H, Health and Miscellaneous. 11. The work is published by Messrs.

Leone Levi, that the state of the finances is given in the quarterly accounts of the revenue, the finance accounts, the statistical abstract, the miscellaneous statistics, the reports of the respective boards, and Mr. Williams's returns; the Customs Revenue being, moreover, given in the Board of Trade accounts, both monthly and annually. The reports of committees generally contain evidence repeating again and again the same facts and opinions. The reports of the Civil Service commissioners give all the examination papers. The treaties with foreign powers are published in English and in the languages of the countries with which they are concluded. As to bulk, it is quite usual to publish folio volumes of 800 pages. The report on the Endowed Schools (Ireland) comprised 1,884 pages.

Smith, Elder, and Co., in monthly parts, forming two volumes a year of about 500 pages octavo each, and gives within this limited compass, and for two guineas per annum, all that is most valuable or needful to be preserved for reference, as regards the general reader, out of the large number of volumes published every Session. 12. The "Annals of British Legislation" have now been in existence for seven years, and fourteen volumes of the same have already been published; but whilst its utility has been fully recognised by many of our most eminent statesmen, experience has shown that a work of this kind cannot be sustained as a commercial operation, not possessing those advantages which are enjoyed by works issued by public authority. 13. Having regard to the success of the "Statistical Abstract," and to the appreciation which has attended even the private enterprise above described, it cannot be doubted that the publication of a Digest of Parliamentary Documents by the Board of Trade would be attended with great benefit; not only by the diffusion and preservation of most valuable information now practically buried and lost, but by the direct saving of a large sum of money—since it would render unnecessary the publication of many copies of papers now printed by both Houses of Parliament, and would greatly extend the circulation of those of which the publication is necessary.

Fine Arts.

PARIS SCHOOL OF BEAUX-ARTS.—The Council of the school has fixed the annual competition and exhibition of the works of the students for the grand prize of Rome a month earlier than usual this year. The decisions are to be made on the 11th of August, and, for the first time, the exhibitions of the works in architecture, painting, and sculpture will take place at the same time. In addition to this annual competition for the privilege of studying at Rome—the Roman scholarship—there are quarterly exhibitions in the school, when honorary prizes are awarded to the pupils; but another kind of competition has just been set on foot, which deserves attention from its novelty and liberality, and which, it is said, promises to work well. The authorities have offered a certain number of silver medals to be awarded by the pupils amongst themselves once a year. The method adopted is as follows:—Each professor selects from amongst the works of his own pupils those which he deems the best. The pupils of each of these schools then elect five out of their own body, and the works of each school are judged by the delegates from its rivals. The pupils in painting of M. Cabanel and of M. Pils obtained in each case a first, second, and third-class prize, while those of M. Gérôme received first and second, but no third prize. In sculpture, M. Durant's school obtained all three; M. Duret's second and third-class prizes only; and M. Jouffroy's one first-class medal. The three architectural schools each earned prizes in all three classes. This is certainly a novel experiment, and of course highly gratifying to the pupils themselves, who are thus formed into a kind of mutual jury.

M. HEBERT, a very charming painter, is said to have been appointed to succeed M. Schnetz as director of the French Academy at Rome.

SCULPTURE FOUND IN CANDIA.—In digging foundations for a mosque near the village of Hicropetros, in the inland of Candia, on the site of the ruins of some ancient buildings, three statues have been brought to light. One of these is of colossal size, and represents a warrior; it seems to be unfinished, but admirably executed. On the cuirass are various emblems, amongst which, and in the centre, is a figure of a man standing by two winged creatures who are placing a wreath on a youth's head. The right hand of the statue is missing. Another of these works is supposed to represent Oceana, and has a small stag crouching at the feet. The third is the statue of a man, without any special attributes.

STAINED GLASS.—The works at Metz are in full activity, and the Belgian journal of the beaux-arts speaks very highly of a window just completed for the cathedral of that town. The subject is the ascension of Saint Barbe and Saint Catherine, supported by archangels, the figures being all larger than life. M. Maréchal, the artist, has availed himself of all the means calculated to give richness and variety to his work, such, for instance, as the use of double glass in parts, and the superposing of one shade or tint over another. The style is that of the fifteenth century, the Augustan age of painted glass.

PUBLIC MONUMENTS IN FRANCE.—A competition has just been opened in Paris for a statue of Marshal Massena, to be erected at Nice, the place of his birth. It is to consist of a bronze statue, about ten feet high, to stand on a pedestal with bas-reliefs. The judges are to be appointed by the administration of Fine Arts. The sum of 25,000 francs is to indemnify the fortunate artist for the whole of his work, statue, bas-reliefs, casting, conveyance, and erection. The pedestal is to be supplied by the authorities, and it is announced that 10,000 francs will be expended upon its ornamentation irrespective of the masonry itself. The sums of 1,000 francs and 500 francs are to be awarded to the second and third designs in the order of merit.—A monumental statue of the famous astronomer Arago, lately modelled by the sculptor Oliva, has just been cast in bronze, and is to be erected at Estagel in the department of the Pyrénées-Orientales, where the illustrious savant was born.—The Municipal Council of Madrid has commissioned the sculptor Medina to execute a statue of the painter Velasquez, which is intended to be appropriately placed in front of the public Gallery of Painting in that city, as a companion to that of Murillo recently erected there.

Forthcoming Publications.

THE APPLICATIONS OF GEOLOGY TO THE ARTS AND MANUFACTURES. Foolscape 8vo., cloth, illustrated, price 4s. By Professor D. T. Ansted, M.A., F.R.S. (*Robert Hardwicke, Piccadilly*).—This work will consist of the course of six Cantor lectures now in course of delivery before the Society, of which merely abstracts are published in the *Journal*. It will appear as soon as the course is concluded.

Correspondence.

CANTOR LECTURES.—WATER SUPPLY.

SIR,—In the Cantor lecture delivered on the 13th inst., of which an abstract appears in your *Journal* of the 17th inst., on "Springs and Water Supply," I observe that the learned lecturer, Prof. Ansted, is reported to have said—"The two rocks that yield the largest quantity of water are chalk and soft sandstone, and in neither of these cases can more than a million gallons per day be expected from a single well. To yield this maximum such wells must be more than a mile asunder." Many popular delusions exist on the subject of wells, and as the above statement, circulated in your *Journal* on such authority, is likely to further mislead the public if left unnoticed, I am sure the professor and your readers will be glad to know that very many wells have been sunk, both in the chalk and red sandstone formations, that readily yield much larger quantities than one million gallons per day, even when situated, as sometimes happens, only a few yards distant from other wells. By way of practical illustration, I may mention the following wells yielding more than one million gallons of water per day, sunk in the chalk, the water being used for domestic consumption:—

Hull, Yorkshire.—A well with bore holes sunk in

chalk, near the town of Hull, yields three and a-half to four million gallons of water per day.

Croydon, Surrey.—Two wells with bore holes in chalk, distant only twenty yards apart, yield one and a-half million gallons per day each, or three million gallons collectively.

Brighon, Sussex.—One well, with adits connected with same, sunk in chalk, yields two and a-half to three million gallons per day.

Amwell, Herts.—The Amwell Hill well, sunk in chalk, belonging to the New River Company, yields two and a-half million gallons per day.

Deptford, Kent.—Two wells, situated not fifty yards asunder, yield about five million gallons per day collectively.

The following wells, sunk in new red sandstone, yield more than one million gallons per day:—

Liverpool, Lancashire.—Green-lane well, sunk in new red sandstone, yields more than three and a-quarter million gallons per day.

Birkenhead, Cheshire.—Well in new red sandstone, yields two million gallons per day.

Pendleton, near Manchester, Lancashire.—Well in new red sandstone and permian, found to yield more than four million gallons per day; not in constant use.

I may add, practical experience has taught me that in suitable situations, by the aid of improved modern appliances and machinery, wells and bore holes may now be sunk, at a very moderate cost, to yield very much larger quantities of water than was at one time possible.

I am, &c., SAMUEL COLLETT HOMERSHAM.

19, Buckingham-street, Adelphi, London, W.C.,
February 23, 1865.

THE MUNICIPAL ORGANIZATION OF PARIS.—SIR,—There is a slight inaccuracy in the report of the remarks I made at the meeting of the Society on the 22nd ult. I am reported to have said, "With respect to the great improvements carried out in Paris, they had been told that a taxation of £3 15s. per head of the population had been the result; whereas the whole rates in respect of the main drainage and improvements of London did not amount to more than 9d. in the pound, or about 10s. per head of the population." What I stated was, that the annual sum raised by the Metropolitan Board of Works for main drainage, new streets, parks, and general purposes, including the coal duties appropriated for the Thames Embankment, did not exceed in amount a rate of 9d. in the pound, and that the whole local taxation of the metropolis for municipal purposes was not more than 10s. per head of the population.—I am, &c., W. H. DALTON.
23, Cockspur-street, February 25th, 1865.

VOLUNTEER FIRE BRIGADES.—SIR,—I very much regret to find that, in my endeavour to be as brief as possible in my remarks on Mr. Young's paper, I omitted to do an act of justice to the London Fire-Engine Establishment, and my remarks being still further condensed makes it appear that I have stated a positive untruth. I therefore beg space to correct this. In the report I am made to say that my brigade never received a penny from anyone for their services. This requires explanation. I stated that Mr. Young appeared to forget that nearly all the Volunteer Fire Brigades were equipped and supported by voluntary contributions. . . . That the brigade I had the honour to represent was more strictly volunteer than any other, as the engines and plant were found by the firm (Brown, Lenox, and Co.), and the uniforms by the men themselves, without subscriptions from anyone, neither had they ever taken a penny for their services; I ought to have added—as all monies received for such service go to a fund in case of accidents or sickness through attending fires. I believe I am quite correct in saying it is the invariable custom of the London Fire-Engine Establishment to reimburse all volunteer brigades the cost out of pocket, and something in addition when

they are really of any service in extinguishing a fire. The late hour at which I was called upon to speak prevented me from going so fully into the question as I should have wished; but I trust that in consideration of the importance of the subject, you will allow me to make a few further remarks, particularly as lately there appears a tendency to underrate the services of the regular brigade; and I exceedingly regret to see my friend Mr. Young getting into the same track, for he says—"It is constantly said that paid firemen will work better than volunteers. . . . If paid men are best, how comes it that volunteers are always asked for when it is desired to do anything difficult or very perilous, say spring a mine—storm a fort—lead a forlorn hope—rescue a shipwrecked crew?"—This sounds very fine, but my friend appears to have forgotten that the volunteers for the above services are always taken from the class that are trained, aye, and often paid for such work, the soldier for springing the mine, and the sailor for rescuing a shipwrecked crew. Would Mr. Young send a party of Deal boatmen to spring a mine or soldiers to man a life-boat? I venture to say he would not; neither would he ask a fireman or fire-escape man to stand on one side and let some volunteer from the crowd enter a building to rescue life or property. I should very much like to see the volunteer movement spread all over the country; and I believe it is in outlying districts they will be most useful, but many years' experience has convinced me that it will not do to depend upon volunteers to protect London or any other large town from fire. I have formed a very strong opinion as to the best means of protecting such places, and shall be glad at some future time to explain my views either by a short paper or letter in the *Journal*, but I feel at present that I have occupied enough of your space—I am, &c.,
WM. ROBERTS.

 Billiard tables, cushions for—316—J. L. Hancock.
 Blowing apparatus—427—S. R. Freeman and A. Grundy.
 Boots and shoes—381—G. Coles, J. A. Jaques, and J. A. Fanshawe.
 Brooches, manufacture of—385—G. C. and J. B. Haseler.
 Buildings, ventilation of—332—C. Beard.
 Cables, metal chains for—431—W. H. Brown.
 Candlesticks—339—A. I. L. Gordon.
 Cane juice, &c., treatment for evaporating, &c.—418—A. Fryer.
 Cannon shot and shells—346—R. Brandon.
 Carriages, construction of—215—S. L. and A. Fuller.
 Cartridges—426—B. Thompson.
 Clarinets—308—J. Park.
 Clog soles, &c., manufacture of—416—R. J. Jones.
 Cupolas and blast furnaces—397—H. H. Grierson and J. M. Rigby.
 Doors, windows, &c., fastenings for—369—G. E. Meek and W. H. Howes.
 Driving bands for machinery, manufacture of—300—G. and D. Iturn.
 Embankments, sea-walls, &c., formation of—380—W. E. Newton.
 Fibrous substances, breaking the stems of and preparing—336—H. B. Barlow.
 Fire-arms, breech-loading—253—W. Clark.
 Fire-arms, breech-loading—299—T. Joyce.
 Fire-arms, breech-loading—358—E. Lindner.
 Fire-arms, breech-loading—421—J. von der Poppenberg.
 Fire-arms, breech-loading—424—J. Purdey.
 Fire-arms, lever powder and shot charger for—302—W. Bartram.
 Fire-arms, locks for—368—J. P. Lindsay.
 Fire-arms, patched balls for—387—M. Peck.
 Fire-places—407—E. B. Wilson.
 Fish-hooks—428—W. A. Hackett.
 Furnaces and boilers—395—J. Cam.
 Garment, combined—423—R. P. Barrett.
 Garments—355—J. Singer.
 Grain, apparatus for separating—348—W. E. Newton.
 Grain, mills for grinding—333—W. P. Wilkins.
 Grease for lubricating, manufacture of—364—J. Desmontils.
 Gunpowder—402—L. H. G. Ehrhardt.
 Guns, breech-loading—265—C. H. Russell and J. Needham.
 Hair brushes—214—C. Roques.
 Hair-pins—325—R. A. Brooman.
 Hops, obtaining the concentrated extract of—306—J. R. Webb.
 Hydraulic lifting apparatus—328—A. Steven.
 Hydro-carbons, supplying a regular pressure of air to burners for consuming—408—E. J. C. Welch.
 Ink, typographic—330—A. A. Hulot.
 Iron, cast and wrought—419—E. H. Newby.
 Iron safes and strong rooms—364—J. Chubb.
 Jacquard apparatus for weaving—329—W. Cockburn.
 Jacquard machines, protector for the needles and cards used in—429—W. C. Ridings, sen.
 Keys, removing dirt from inside the barrels of—238—R. Helsham.
 Lead, purification of—310—J. A. Phillips.
 Leys, treatment of spent or used—297—T. Routledge.
 Life belts, swimming belts, &c.—341—C. Kilburn.
 Looms—293—J. Maynes.
 Looms—377—R. G. Hazard.
 Looms, heads for—347—A. A. Lärmuth.
 Mathematical compasses—235—J. E. F. Ludlake.
 Metallic casks and drums—327—G. Duncan.
 Metal pipes, mode of making—356—W. Anderson.
 Miners' safety lamp—353—R. C. Thorp and P. Young.
 Money, tickets, &c., apparatus for counting—383—J. Schneeshr.
 Mooring anchors—420—J. Trotman.
 Motive power, obtaining—331—J. I. Watts.
 Netting, manufacture of wire and other—360—R. A. Brooman.
 Oil for machinery, production of—388—J. Hall.
 Ores, extracting gold and silver from—391—W. Crookes.
 Ores, furnaces for smelting iron—374—E. Leigh.
 Ores, furnaces for smelting or reducing—411—H. J. Walduck and E. Barton.
 Paper-hangings, manufacture of—322—J. Booth.

- Peat for fuel, manufacture of—319—R. M. Alloway.
 Pencil cases, manufacture of—298—W. Vale.
 Pencil-holders and pen-holders—352—W. E. Wiley.
 Penholders, manufacture of—406—F. C. Vannet.
 Presses, fly or embossing—208—J. Bailey.
 Pressing irons heated by gas, ventilation of—350—S. E. Rosser.
 Pumps—436—G. T. Humphris.
 Railway chairs, &c.—318—R. Richardson.
 Railway engines, &c., bogie trucks for supporting—404—W. Adams.
 Railways, ships, &c., signal applicable to—367—A. W. Banks.
 Railway switches, &c., working and controlling—432—M. Lane.
 Resinous wood, extracting turpentine and tar from—403—J. A. Pas-torally.
 Rivetting, machinery for—400—H. M. Kennard.
 Satin white, substances to be used in place of—371—J. Dale.
 Sewing machines—304—W. Clark.
 Sewing machines—430—A. V. Newton.
 Sewing machines, operating the working parts of—370—A. V. Newton.
 Sewing machines, single thread—396—A. V. Newton.
 Sheep shears—284—J. Ball.
 Ships and vessels—337—R. Brassens and F. A. Le Mat.
 Ships, apparatus for discharging coals and other cargo from—359—G. Elliot and H. Coxon.
 Ships, armour-plated—438—G. T. Bousfield.
 Ships, forts, &c., armour-plated—292—C. Langley.
 Stamps and labels, apparatus for affixing—379—H. W. Hart.
 Stay busks, &c., fastenings for—349—G. Twigg.
 Steam, application of hydro-electricity to—273—J. Fletcher and D. Hamer.
 Steam boilers—401—R. W. Thomson.
 Steam boilers, combustion of fuel in the furnaces of—311—F. C. Hills.
 Steam boilers, preventing the explosion of—305—J. Westerby.
 Steam engines, expansion gear for—415—W. F. Batho.
 Steam generators—345—J. Lake.
 Straw, &c., machinery for cutting, sifting, &c.—340—J. Cornes and W. Simpson.
 Strained wire or rod fencing, standards for—76—W. Bayliss.
 Telegraphs, insulating material for—392—W. A. Marshall.
 Textile fabrics, rendering unflammable—313—E. Hodin.
 Tooth powder—301—B. L. Mosely.
 Vermin traps—312—R. S. Baker.
 Vessels, &c., armour-plated—296—J. S. Jeffreys.
 Water, apparatus for heating—390—A. McLaren.
 Waterproofing skins, &c.—413—G. Harton.
 Wearing apparel, skirt borderings and linings for—361—W. Staats.
 Window safes—326—R. Shaw.
 Wood, &c., varnish for preserving—315—R. A. Brooman.
 Wooden surfaces, preservation of—363—J. C. C. Halkett.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MARCH 15.—"On Marine Engines from 1851 to the present time." By N. PROCTOR BURGH, Esq., C.E.

MARCH 22.—"On the Preservation of Food, especially Fresh Meat and Fish, and the best form for Import and Provisioning Armies, Ships, and Expeditions." By G. C. STURT, Esq.

MARCH 29.—"On Window Horticulture, and the Cultivation of Plants and Flowers in Cities and Crowded Localities." By JOHN BELL, Esq.

CANTOR LECTURES.

The concluding lecture of the Second Course, the subject being "The Applications of Geology to the Arts and Manufactures," by Professor D. T. ANSTED, M.A., F.R.S., will be delivered on Monday evening, at Eight o'clock, as follows:—

MARCH 13TH.—LECTURE 6.—On Metalliferous Veins or Lodes and their Contents, and on the Extraction of Metalliferous Minerals from Lodes.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

Proceedings of the Society.

CANTOR LECTURES.

SECOND COURSE.—FIFTH LECTURE.—MONDAY, MAR. 6.

IRONSTONE AND COAL.

Professor ANSTED first pointed out that iron and coal were the chief sources of material wealth, and that Great Britain was especially provided with these minerals. The circumstances under which iron ores and mineral fuel are found, the extent of the deposits, and the way in which they may be obtained, were the subjects to which he would now direct the attention of his audience. Iron is widely disseminated, and forms part of almost every substance with which we have to do. But although thus common, the ores are not universal. In most of them iron is in combination with oxygen. These include mag-
